i have heard many say that run the cables direct /but i also heard lots of issues with ground loops so u need the isolation/ they knocked out my brand new ts 2000
but luckily they replaced the radio/after that always use isolation

I use the phone patch all the time for PSK31. I just run straight cables
from the computer to the radio. I use fldigi for the software. The only
tricky part is the stability of the VFO, I'm considering buying a
crystal for the PSK frequency to lock it down.

Respectfully,
Cliff White, W5CNW

That's what a lot of hams do, order a crystal and select "FIX" on the
FUNCTION switch.

The crystal, when installed and selected, replaces the VFO. The
operator's manual has the formula for calculating the crystal frequency.

For example, if one wanted to transmit and receive, crystal control
(Function switch FIX position) on 20 meters at 14.070Mhz, the crystal
frequency would be 5.430Mhz. The formula and simple examples are on page
21 in the TS-820 operator's manual.

The "5.5" in the following example is the VFO's output frequency at the
bottom of ALL bands. The "14" is the Band Switch setting for 20 meters.
The "14.070" is the transmit and receive frequency you plan on using.
The same crystal can be used on other bands as well, again, see the
operator's manual for details. The crystal frequency ranges are from
5.500Mhz to 4.999Mhz, same frequency range the internal and external
VFO's operate on, regardless of the band switch setting.

5.5 + 14 - 14.070 = 5.43Mhz

When using "FIX", the internal VFO is "disabled" in both transmit and
receive. The crystal controls both transmit and receive.

International Crystals in Oklahoma City, OK can provide the crystal.
They have an 800 number and they take all major credit cards.

The sound card circuits are simple and easy to build. The parts can be purchased from Mouser or on eBay and built on a Radio Shack solder perf board. No power is required if VOX is used to key the transmitter. There are websites that show simple sound card audio interface circuits.

I am thinking about doing this with my 520S too. Do I have to order a crystal using the formula for CW or USB?

Common sense would say you order the crystal in the MODE you operate in.
If you operate in USB then use the USB formula, LSB use the LSB formula.
The crystal, regardless what position the FUNCTION switch crystal
control setting is set to, replaces the VFO.

The Function switch crystal control settings operate as follows:

FIX = crystal control in both receive AND transmit
FIX R= crystal control in receive, VFO control in transmit
VFO R = crystal control in transmit, VFO control in receive

Once the Function switch is set to the desired position, the FIX Channel
crystal select switch determines which crystal is used. Naturally, the
operator should remember what socket the crystal they want is plugged
into. All of this is discussed in the 520 operator's manual.

42774. BS-8 conversion to BS-5

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-12 13:28:14 UTC
From: n3kvl
Topic: 42774 Message: 42774

Hello All,

I am about to buy the parts necessary to convert the BS-* to the BS-5 spec for use with my TS520S.

I don't seem to be able to find a part a Kenwood p/n L31-0286-05.

This part comes up in a search with a part company http://www.pacparts.com/

Anyone have any luck with this seller?

Thanks
Archie

For those who are deciding what formula to use when ordering a crystal
for FIX'd operation using your TS-520 or TS-820 on "PSK-31", the
following is provided.

BPSK-31, the typical PSK-31 mode used today, doesn't matter what
sideband you are using. You can operate on LSB even if the other BPSK31
station(s) are operating on USB and neither one will know the difference
unless you tell them.

QPSK, on the other hand, requires that BOTH stations use the same
sideband. If one station is using LSB and the other station is using
USB, they will not be able to communicate. For the 2 stations to
communicate using QPSK-31, they both MUST use the same sideband, USB/USB
or LSB/LSB.

Simply select the desired/required sideband Mode and configure your
sound card software accordingly and have fun.

"Remembering" it is a great way to have to yank the cover off every now
and again to look inside to see which crystal is where.

WRITING IT DOWN somewhere, like a log book or such, is another possible
option which might save some wear and tear on the case screws, don't you
think?

42779. "New"TS-530S dead on 3 bands

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-13 15:03:13 UTC
From: Craig Roberts
Topic: 42777 Message: 42779

I've apparently become an addict. Not satisfied with my nicely working (except for a glitchy VOX) TS-530S, I acquired another one. As you will soon understand, I couldn't pass this one up. It arrived in its original, unmolested boxes (outer and inner) and appears to have been used very little, if at all. There's not a mark on it, inside or out. And that, predictably, is the problem.

The radio works fine on 80, 20 and 15 with full output. On 160, 40 and 10, however, the thing's stone cold dead. (I didn't check out the WARC bands, come to think of it). Nothing, nada, zip, zero on receive and transmit. Given the fact that this rig apparently sat on a shelf for nigh onto 30 years, I suspect tarnished bandswitch contacts or some such. Is there anything else that might cause this anomaly and are all the contacts I need to attend to accessible without undue disassembly of the radio? I'm not afraid of diving in, but saving time and effort is attractive.

Thanks and 73,

Craig

Hi have a 820 with DG-1 fitted.

Fault is at TUNE up - 1.8 3.5 7 14 21 are great. great ALC peak & IP Dip.
Switch to any 10 meter no ALC. Digital display OK when cold but all over the shop when warm - Transmit Freq rock sold on HP Counter - not to fussed about it at this stage - it is isolated from radio for now.
Any pointers on where to start - I'm thinking my 10m band crystal osc are not firing up.
Radio has new driver and finals and nuetralised on 10m earlier this.

Craig,

The rig should STILL receive the "WARC" bands...it will not transmit.on them until either way of activating them is done.

I suspect that you have no/poor contact on one or more of the "band switch wafers," due to oxidation...common problem. The first thing you should do is obtain a good contact cleaner/lube...I use DEOXIT D5 and some "canned air" or "air duster" to blow off the residue...others have their favorites. Remove the top and bottom covers...do this with power OFF and rig UNPLUGGED!!! Remove the screws holding the cover over the final amplifier cage. Short to ground from the top of the plate choke...that tall white ceramic do-hicky...with the fine wire wrapping on it...it between both final amp tubes. USE INSULATED TOOL!! Then check with volt meter...to make sure that there is NO voltage...otherwise you'll get a rather shocking surprise. Remove both final amp tubes. Use cleaner/lube according to directions on the "wafers" on the RF board and in the final cage. Rotate switch through its travel numerous times...spray cleaner/lube again...rotate band switch through travel...blow off all wafers...Make sure all of what ever you may use has evaporated...some of the cleaner/lube stuff is flammable!

I suspected as much. Thank you, Joe.

As for HV precautions, I appreciate you reiterating them. I used to repair CRT-type televisions so I know ALL about the dangers of muscular currents -- but it never hurts (literally) to be reminded.

Here's an entry in DL9AI's online "Kenwood TS-830 Survival Guide" that may prove useful to me as well as the correspondent with the ALC glitch on 10 meters. I just discovered this great resource a few minutes ago:

/Problem: Intermittent ALC indication [TX] on only one band /

/The bandswitch is usually the culprit. This occurs most often on the 7 MHz band-switch position, on the two, rear-most bandswitch sections in the RF Unit. /
/
Cause: The bandswitch (also) has dissimilar-metal crimp-connections that turn into semi-insulators due to electrolysis. This takes place between the bandswitch's riveted-on,, tin-plated, stationary contacts and the copper-foil on the printed circuit board [PCB]. /
/
Fix: Apply a small amount of conductive-paint where the stationary switch contact touches the copper-foil on the PCB. The conductive-paint will be drawn, by capillary-action, into the problemarea where the two, dissimilar-metals touch each other.
/

Anybody tried this?

There is a rule I ***follow*** when working with high voltage....and it has saved my bacon several times...The good old
'one hand rule . When working in or around high voltage, **ALWAYS** keep one hand behind your back! The theory behind this rule (From my commercial FM station engineering days!) is to be dangerous, voltage has to flow through you...if it does, it can affect your heart...and it usually stops it..ie: death. If you get hit only on one hand...your arm may go numb (read dead!), and you may suffer some pretty serious burns, but you will be alive to do it again!

Thanks Joe:

I tend to stay away from the HV stuff... However, Am going to have to do something with my Valiant... Heard a crack, then the fuse blew... Haven't taken it apart yet... Guess I would rather sell it, "as is"... Takes up way too much room on the desk... Very 73 ... John ... KB9PBM ...

Heh.......

I worked with a fellow once, that you learned very quickly, that if he was under the hood of a car, and it was running, you kept an arm's length away from him. He would grab a spark plug and then grab you as you walked by. I can assure you, it was an uplifting...no...HAIR-RAISING, experience!

Thanks to his other two vocations, my uncle's hands were so thickly calloused that he could (and did) handle 120 and even 220 volt live wires with little apparent distress. In fact, he would test live circuits by touching contacts and wires to detect the tell-tale "tingle." They were of such a minor nature to him that he would re-wire switches and sockets without cutting power to them, though -- to be fair -- while warning me strongly not to follow suit.

My late, favorite uncle was a farmer, carpenter and electrician --
highly experienced and skilled in all three disciplines. He taught me
basic electrical theory and household wiring when I was about 10 or so,
cautioning me repeatedly about the magic force's dangers. In practice,
however, his methods were of the "do as I say, not as I do" variety.
Thanks to his other two vocations, my uncle's hands were so thickly
calloused that he could (and did) handle 120 and even 220 volt live
wires with little apparent distress. In fact, he would test live
circuits by touching contacts and wires to detect the tell-tale
"tingle." They were of such a minor nature to him that he would re-wire
switches and sockets without cutting power to them, though -- to be fair
-- while warning me strongly not to follow suit.

Nevertheless (and predictably) I was determined to imitate my hero and
so -- well -- you can guess...

I did this exactly once! That is not to say that I haven't been bitten
a few times since, but certainly not so deliberately.

73,

Craig

Topic: 42780 Message: 42792

Hi Stuart

I have a 520SP which had same symptoms - ALC fine on all bands except 10m.

What transmit frequency do you see on the HP if you try to tune on 10m (I appreciate you don't have ALC to help set Drive, but you can get it close peaking background noise on receive)? What power out are you getting on 10m compared with other bands?

Terry K9TW here was incredibly helpful walking me through measurements to try to diagnose problem (I am an old electronics and radio hobbyist, but missed the valve era!). In my case though the problem was that the 28MHz drive coil on the RF coil board had ferrite slug in completely wrong position, near base of former. When I unscrewed the slug (having freed it up with tri-flo penetrant) and moved it up the former the ALC sprang to life. After peaking it I could get full scale ALC with the carrier just past the 12o'clock position. Before I was only getting a few watts RF out on 10m, but after aligning Drive coil I am getting around 100W.

Your issue may not be the same (another possibility is 12BY7A Driver which when it dies loses the 10m band first - I replaced mine when first trying to fix problem but of course made no difference) but worth checking that Drive coil. Make sure you have a correct plastic hex tool for the slugs.

Stuart:

Can you peak ALC with RX back ground noise or Marker signal and then load into dummy load for approx 80-100 watts out on any or all of the 10 meter bandswitch positions? Since you say TX frequency is rock solid you must have some RF output into dummy load on each of 10 meter bandswitch positions? If you have accurate TX output freq on all 10 meter bands you have to have some level of VCO signal at Transmit Mixer to mix with the TIF signal to produce the 10 meter TX signals.

If you had one 10 meter band position out I would suggest you look at the associated Het Osc crystal on the PD board. It is possible to have a bad xtal or bad solder connections at the xtal.

However very unlikely to have all the 10 meter Het Osc xtals to be bad. Need to ask yourself what is common and one thing would be 9 vdc switched to Conn PLL-3 from the bandswitch. Without good 9vdc at this connector you can have problems with these Het Oscillators and with B1 thru B4 feed to the Counter Assembly board. B1 thru B4 control the bandswitch filters at the output of the 2nd mixer on the counter assembly board. If B1 thru B4 are not getting approx 8.4 vdc they wont switch on the BPF switching diodes.

The required 9vdc comes from the wiper of the bandswitch S3 and is applied to each of the 10 meter switch contacts. Very unusual to have all the 10 meter bandswitch positions to have bad contacts. The wiper cant be bad as it also supplies the other bandswitch positions that you report as working.

You can measure the 9vdc at PLL-3 Pins 2 thru 5 and if low can temporarily apply 9vdc bench supply or transistor battery to see if it corrects the problem.

Good Morning All,

I finally had time to get back down to the shack, and do more testing, her is what I found>

I started by changing jumpers, and checking the dummy load., which is a 1 quart oil filled, paint can type.

SWR-1.02:1
Resistance-49.1 ohms

Everything seems ok there.

Initial rig settings:

Mode-Tune
Mic Gain 6
Car at 10 o'clock
AGC slow
Load CCW
Plate approx. band
Drive 12 O’clock

Checked bias-60 Ma

Tuning into the dummy load, staying in the “Tune” position.

Trying several different bands.

On 20m:

Drive-Peaks normally
Plate-Dips in the 12 m band range
Load- Peaks barely off of CCW

160 m

Drive peaks normally
Plate almost imperceptible dip way CCW
Load peaks at about 11 O’clock

80 m

Drive- In order to peak the drive Car needed to be raised to just barely past 12:00
Plate- No Dip
Load-Very little peak

40 m

Car up to 3 o’clock to get peak
Plate no dip at all

This is where I got nervous and just stopped. I know this is a lot of information, but does it seem to point in any direction to anyone?

Tom

I think you are saying only tried loading in Tune Position. Is that correct?

If so, try in CW position. Just need to have meter on Ip position and hand on Plate Tune and tune to minimum plate current (dip) quickly. If you have high plate current and cant dip return to standby position quickly. Can reduce CAR Level and then try again,

If you can get normal loading in CW you may have problem with R15 56K ohm SG dropping resistor that supplies reduced screen grid voltage to your finals.

I did not tell you to wiggle or unplug and plug PLL-3 connector on PD board because I believe you report normal 21mhz operation and the Het Osc for 15 meters gets its 9vdc from this same plug as all the 10 meter Het Osc do.

Hey Folks:

In the hospital here. Not by plan or desire! Looks like I am going to be a Coumadin man (rat poison! Better than the alternative!

My wife brought my lap top up last nite, but they are keeping me busy so I will be slowing down the help I can give for awhile. Hope to get out by Monday or so. Been here since Weds morning.

Very behind on my other email account messages and for those helping off list sorry I may have to wait until get home to resume our work together as I have no access to any of my notes so dont want to advise you strictly off top of my head.

Take care
73s Terry K9TW

I set my signal generator to 28.000mhz with 1000hz test tone 5uV and was able to receive and peak rx with drive.
Set 820 to tune and a tiny amount of RF is making out to my Freq Counter and 28Mhz
Still no ALC function just for the 4 10m segments all othe bands OK.
I think it will be a dry joint or something mechanical in a switch as this fault has only just happened

All my valves / tubes are new or old new

Subject: [TS-520_820_530_830] Re: 820 No ALC on 28-29

Hi Stuart

I have a 520SP which had same symptoms - ALC fine on all bands except 10m.

What transmit frequency do you see on the HP if you try to tune on 10m (I appreciate you don't have ALC to help set Drive, but you can get it close peaking background noise on receive)? What power out are you getting on 10m compared with other bands?

Terry K9TW here was incredibly helpful walking me through measurements to try to diagnose problem (I am an old electronics and radio hobbyist, but missed the valve era!). In my case though the problem was that the 28MHz drive coil on the RF coil board had ferrite slug in completely wrong position, near base of former. When I unscrewed the slug (having freed it up with tri-flo penetrant) and moved it up the former the ALC sprang to life. After peaking it I could get full scale ALC with the carrier just past the 12o'clock position. Before I was only getting a few watts RF out on 10m, but after aligning Drive coil I am getting around 100W.

Your issue may not be the same (another possibility is 12BY7A Driver which when it dies loses the 10m band first - I replaced mine when first trying to fix problem but of course made no difference) but worth checking that Drive coil. Make sure you have a correct plastic hex tool for the slugs.

Hello Terry,

We have never met but I encourage you to keep your chin up. I speak from experience

as I have had a triple by-pass and have 13 stents. My age here is 75. My advice after you recover; exercise,

exercise, exercise; if your doctor allows it. We have an excellent cardiac rehab program

here and I’m pretty much a life member. I have been told that walking is the best exercise and it

is cumulative. Ten minutes here and 20 minutes there all adds up. My 13th stent was

memorial day and I start back in rehab today. Good luck and God bless…

Hey Folks:

In the hospital here. Not by plan or desire! Looks like I am going to be a Coumadin man (rat poison! Better than the alternative!

My wife brought my lap top up last nite, but they are keeping me busy so I will be slowing down the help I can give for awhile. Hope to get out by Monday or so. Been here since Weds morning.

Very behind on my other email account messages and for those helping off list sorry I may have to wait until get home to resume our work together as I have no access to any of my notes so dont want to advise you strictly off top of my head.

Take care
73s Terry K9TW

Ask about Xarelto, Terry. Modern replacement for Cumadin , and you don't have to get those PT/INR test all the time!

42819. TS-530s Plate Shaft Coupler

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-14 19:14:48 UTC
From: ThomasA
Topic: 42819 Message: 42819

Hello All,

Well after much good advice from this group I think maybe I am making progress on the problem with my rig.

Suddenly last week when tuning I noticed that the pointer on the "Plate" knob was no longer pointing in the 20 m range as it normally did.

Being new to the hybrid rig, I instantly thought that I had smoked something while trying to tune.

I consulted this forum and have received loads of helpful advice.

I followed one bit of advice and took the top off of the rig, the shaft couplers on the "Plate" control are both loose.

Loose enough I can hold the shaft easily with my fingers, and turn the knob. I was happy to make this discovery.

My next question is of course, what are the proper steps to do in order to correct this?

I am sure everything is way out of line by now, neither of the couplers look cracked, just loose.

Tom

Tom,

Several choices here:

Tighten up a couple of the set screws...one on the far end..one on the near end...tune up on.... say around 14.175(please use dummy load)....loosen one or both set screws on the near side...rotate knob/pointer to about mid scale for 20meters...while holding the far end from moving....snug up all screws.
or

Remove top and bottom covers...remove final amplifier cage cover...power OFF and rig UNPLUGGED FIRST! Rotate the air variable cap.
so the plates are approx 50% meshed...ie. the movable part is an approx 90degree angle...with the plates to the left...open space to the right.
Loosen screws on shaft...hold far end from moving...rotate knob/pointer to approx middle of the 20meter(14Mhz) band...SNUG up the set screws.

I prefer the first myself

From: Dale Parfitt
Topic: 42823 Message: 42823

I am repairing a TS-900 and have the service manual. The RF Gain pot is described as dual gang 1K (A). Some Other pots are listed as (B). The audio gain pot is listed as (A).
If Kenwood carried this description to other more common radios, does anyone know if (A) is audio taper?
The resistive elements are broken and vaporized or else I would measure them.

Hi Terry,

My best whishes to you and I hope that you have a speedy recovery. Take care of you that this is the most important thing now.

I am not a very active member for the moment because I must learn a lot from persons like you, reading all the good explanations and helping so much to solve the problems that may affect our Kenwood's. I am a proud ownwer of a TS-830S Gold Label and an AT-230 tuner.

God bless you and your family.

David, EC4ACH, from Spain.

Tom,

Good find! Just remember that you are going to tighten the grub screws into nylon that has most prob gone a little hard and will be subject to splitting if you over tighten the screws. Once you have aligned check all bands and see how it goes from there, don't screw the covers back on until your happy with position of indicators on front panel.

Hello All,

Well after much good advice from this group I think maybe I am making progress on the problem with my rig.

Suddenly last week when tuning I noticed that the pointer on the "Plate" knob was no longer pointing in the 20 m range as it normally did.

Being new to the hybrid rig, I instantly thought that I had smoked something while trying to tune.

I consulted this forum and have received loads of helpful advice.

I followed one bit of advice and took the top off of the rig, the shaft couplers on the "Plate" control are both loose.

Loose enough I can hold the shaft easily with my fingers, and turn the knob. I was happy to make this discovery.

My next question is of course, what are the proper steps to do in order to correct this?

I am sure everything is way out of line by now, neither of the couplers look cracked, just loose.

Tom

Subject: [TS-520_820_530_830] TS-900 and Kenwood pot styles

I am repairing a TS-900 and have the service manual. The RF Gain pot is described as dual gang 1K (A). Some Other pots are listed as (B). The audio gain pot is listed as (A).
If Kenwood carried this description to other more common radios, does anyone know if (A) is audio taper?
The resistive elements are broken and vaporized or else I would measure them.

Hey Folks:

In the hospital here. Not by plan or desire! Looks like I am going to be a Coumadin man (rat poison! Better than the alternative!

My wife brought my lap top up last nite, but they are keeping me busy so I will be slowing down the help I can give for awhile. Hope to get out by Monday or so. Been here since Weds morning.

Very behind on my other email account messages and for those helping off list sorry I may have to wait until get home to resume our work together as I have no access to any of my notes so dont want to advise you strictly off top of my head.

Take care
73s Terry K9TW

Thanks to all for your words of encouragement. It is very touching to realize how many friends I have on this forum. I am lucky to be alive and to have found this group. I had multiple pulmonary embolism in both lungs. My family doctor of 40 years started me on Heparin and Coumadin.

I asked him about the new blood thinners and he just dismissed them as too expensive and that he had successfully administered Coumadin for years with many patients. I appreciate that he is comfortable with this 1950s protocol.

Well my cardiologist showed up late afternoon and is taking me off the Coumadin and starting me on Xarelto. Just took my first one.

So I am happy camper and looks like may get to go home tomorrow. Still no smoking gun found. Usually caused by deep vain thrombosis in legs but ultra sounds were negative and no signs of AFIB. So important thing now is to prevent recurrence as this is a killer.

So will take the exercise advice to heart literally and good advice from Jim regards the Xarelto.

Once again thanks to all of you.

I will be back once get this behind me. There are plenty of you to help each other keep these Kenwoods we all love running.

Got to go now and try to get the cover put back on this Spectrum Sigma Infusion Pump. I dont think it is caled correctly !!!

Hi Terry,

My usual salutation is "I hope this finds you well" but in this case let me join others in wishing (and praying) that you are soon better.

In regards your initial post; my guts tell me that you "operating off the top-of-your-head" is as good as most techs operating with their whole reference library. It is also curious to note that the group members on this reflector are now collaborating to fix the guys who fix the rigs. Good luck and God-Speed in your recovery. My best regards to you and those you hold dear.

Hi Terry,

So you are in hospital. Indeed. Nah, we can't have that. What are you doing mate. The whole forum will go south. Hundreds of Kenwood hybrid owners will be tearing out their hair. Knarling of teeth will be heard worlwide. I am going to shut down my TS-830S and cover it with a black cloth covered in ashes whilst in mourning.
Can't do anything more.
Get better quick mate.
From a friend " Down Under "

Subject: [TS-520_820_530_830] Hospital

Hey Folks:

In the hospital here. Not by plan or desire! Looks like I am going to be a Coumadin man (rat poison! Better than the alternative!

My wife brought my lap top up last nite, but they are keeping me busy so I will be slowing down the help I can give for awhile. Hope to get out by Monday or so. Been here since Weds morning.

Very behind on my other email account messages and for those helping off list sorry I may have to wait until get home to resume our work together as I have no access to any of my notes so dont want to advise you strictly off top of my head.

Take care
73s Terry K9TW

This is not a joke. Some years ago, I was hospitalized, and a friend brought in a two meter handheld for me to play with while I was recuperating. EVERY TIME I hit the transmit button, the monitor in my room would start BEEPING an alarm !

I had to be content just to listen to what was going on. Not fun !

Maybe things are a bit more immune to RF now days.

42844. How firm/stiff should the drive and plate knobs turn?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

Greetings all!

I did a search and found others had a similar situation, firm/stiff drive and or plate knobs.

My radio sat for the last 30 years before I bought it from the guy who never used it. He got it from a friend, my guess is, when it was 3-5-ish years old.

I opened it up and it looks remarkably clean inside. There was only a tiny amount of black grease on the shaft where a tensioner rides. There were no signs of excess grease, dirt etc. I did spray DeOxIt at all rod connections/bushings/bearing etc. I can see no grease at all on the ball bearings at the vari caps' shafts and they look very clean.

I was told not to get any oil/grease on the vari caps, so didn't. I can't see anywhere to DEOxIt, or lube, that isn't already moving at what appears to be as freely as it is going to.

When completely assembled, both knobs take some force/torque to turn. I was expecting something about as free wheeling as the volume knob on my Honda...but it's not even close.

So, is this normal, or do I still have issues here ???

Thanks for your help,

Chip

Chip,

First..what rig do you have?

The VAST majority of the hybrids have a kind of a gear reduction for the "PLATE" control and a rather straight forward shaft/chain drive arrangement for the "load" & "drive" controls.
The "plate" control can be "freed up" by partly disassembling the "reduction drive" It's packed with grease...and after that long a time of no operation...it turns into semi set concrete. Ask any TEN-TEC owner! The other controls...it's OK to apply a SMALL amount of a non-contaminating oil to the bearings...just NOT on any of the "wipers" on any of the air variable caps.

I suggest that you download a service manual for what ever rig that you have...you can find good ones at: n6wk.com that is Gordon's web site..a member/moderator of this board. It will show you an "exploded view" of the "reduction drive." There are small ball bearings in the reduction drive. I can give you some more specific info...when I know the model of your rig

My post wasNOT meant as a joke...it WAS meant, as a "light-hearted" attempt to cheer up Terry. It wasobviously misinterpreted by AG3Y...I know full well about these things. I have spent most of my adult life(34 years) as a Firefighter/Paramedic, unfortunately...guess what.....some "other ham radio operator" was talking on his radio(mobile).... was NOT paying attention....could not SEE or HEAR the big fire engine...with it's lights and sirens going...ran through an intersection and hit right where I was sitting. So now, I have a plate and six screw holding my neck together, my right shoulder will NEVER be the same...I have limited function of my right arm.....and a back that will NEVER be right, spent a few months learning how to walk again.....I hobble around in the shape of the letter "V" and have to use a canes to even move from one room to the other. I was forced to retire...because as you always hear...about cell phones and, texting...how about "hams" "talking and driving."

Again, my prior post was HUMOR and, OBVIOUSLY...by some persons standards, NOT humorous. I have probably created a "fecal matter storm" and really
don't care. So, I can cover all the bases: Apologies if I offended anyone in the slightest.

Thanks for the response Joe !

I guess I forgot to mention, this is a TS-520, my apologies for that screw up.

Right now after reshooting DeOxIt, the Load is the smoothest and most easily turned, feeling closer to what I might expect. Then the Plate is the next smoothest, followed by the Drive which is the stiffest. None are as free as a radio volume switch, to give a comparison. Visually examining, everything appears to be straight line shafts leading to the "business end" of the caps etc. The Drive has that overhead rod with the chains leading to the caps. Disassembly of that scares the crap outta me as I doubt I'd get everything lined back up correctly again.

It is entirely normal for the Drive control to be stiff. I should turn smoothly, but it should be relatively firm compared to load. Plate should also be firm but smooth. Load should have the least turning resistance, almost as free as a volume control.

Chip,

....the controls should offer "some" resistance..and operate smoothly....it is difficult to say from one to the next what "hard to turn, stiff"...etc...really means. The "radio volume
control" really can not be used as an apples to apples comparison....if all the controls operate smoothly...no binding...don't cause "noise" or other problems.. when operated...etc...why worry...operate the rig! I don't know..but maybe this rig(s) is/are older than your children....I know mine are

No screw up Chip. A word of warning...IF you plan on doing some service on this rig...especially adjusting the various coils...PLEASE ask some questions here..or go to the "files" section and look for info on those darn coils..before you break them......

Thanks Louis and Joe!

These do move smoothly and do now move with less resistance than prior to using the DeOxIt. It's the varying resistance between the three that was sending me to question if there's more maintenance needed.

Now the next scarey thing to investigate.... why I have three "modules" in a small envelope that has 10M Cyrstals written on the outside ??? :-(

Then the Plate is the next smoothest, followed by the Drive which is the stiffest. None are as free as a radio volume switch, to give a comparison. Visually examining, everything appears to be straight line shafts leading to the "business end" of the caps etc. The Drive has that overhead rod with the chains leading to the caps. Disassembly of that scares the crap outta me as I doubt I'd get everything lined back up correctly again.

Chip,

  I hope that your rig has not been "CB HACKED." Compare the frequency of the crystals IN the rig with the stated frequencies of the crystals
noted in the service manual.

42853. TS-820 not showing trasmitter output during tune procedure

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-15 21:14:42 UTC
From: Barry
Topic: 42853 Message: 42853

I passed my Tech license exam this morning and missed General by 2 questions, doggone it... but a friend of mine came over with some of his equipment this afternoon, and we're trying to go through the tuning process for my TS-820.

According to Section 4 of the Operating Instruction Manual, we've checked Table 1 and Table 2 for receiving and transmitting settings. Table 3 we're getting plate current on ip meter readings - 60 milliamp plate current - but when we go to the second step to turn to TUN, we can receive but when trying to send the ALC meter setting shows nothing. No meter movement at all.

If we skip that step and go to TUN again to the ip meter to dip the plate current, it is not showing any meter reading, either.

Skipping that step and going to CW with RF, there's no effect turning plate and load controls.

The last 3 steps of tuning procedures in Table 3 we get no response.

We do get High Voltage readings on the meter, though. There is like an 800 reading on them.

Is there something we're missing or not doing? It seems to be receiving perfectly well. We tried changing to USB and LSB to see if we could transmit and have my Yaesu unit in the same room trying to see if we can receive anything on it, but we're not getting any input on it.

This is the first time I've tried to do much with the 820. Thanks for any insight at all you can give me as to what I might can do. This is the first ham radio I've had, so go easy on me...

...and thanks very much for your help previously as well!

Barry

Barry:

Congrats on getting your tech! Don't feel bad about missing the General, I missed Tech the first time I took the test. Of course at that time the two written exams were the same.

First realize that with SSB you are not going to get much of an IP reading with the micophone gain turned all the way down as they say to do and even after you turn up the mic gain you still have to have some audio input to goe some RF output.

The way you test SSB output levels is to inject a tone, such as 1000 hz, into the microphone jack and observe RF output levels as you transmit.

Second, different bands require different CAR settings. If you are on 10M, try turning the CAR control up past the halfway setting they recommend for an initial setting. And you need to do this even just to get some ALC.

I assume you have a dummy load of some kind?

Good Luck!

Robert

Hi Joe,

I found the other 4 crystals the schematic says there should be in here and they look exactly like these in the envelope, all made by Trio. I found these on a board on the bottom side of the radio. The four that match are closest to the outside of the board. On the inside edge of this board are three "modules" that have an aluminum "case" to them, which is different than the crystals on the board or in the envelope. On those "cases" there is stamped TS 520, nothing else I can see. The owner I got it from, the one who supposedly didn't use it, was real big into CB. He showed me his CB stuff while I was there. I took a picture of what I am talking about although it's difficult to see the aluminum "modules" on the inside of the board. If I can figure out how to upload it, I will.

> > Right now after reshooting DeOxIt, the Load is the smoothest and most easily turned, feeling closer to what I might

expect. Then the Plate is the next smoothest, followed by the Drive which is the stiffest. None are as free as a radio volume switch, to give a comparison. Visually examining, everything appears to be straight line shafts leading to the "business end" of the caps etc. The Drive has that overhead rod with the chains leading to the caps. Disassembly of that scares the crap outta me as I doubt I'd get everything lined back up correctly again.

42857. Re: TS-820 not showing trasmitter output during tune procedure

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-15 22:27:17 UTC
From: Barry
Topic: 42853 Message: 42857

Not sure if my message went through - I've had Internet trouble today for some reason.

Thanks very much, Robert! 2 questions, doggone it, and I'd have my General in the same day. I was at least happy to get the Tech!

We plugged the same endfed antenna into the 820 that my Yaesu rig uses. Its SWR was showing about 1 to 1.5 to 1 today. We weren't using a dummy load - we were going straight into the antenna, and I couldn't get any meter reading on trying to talk into the mic.

I was pretty disappointed - I was hoping to see what the 820 will do because the friend of mine has an 830. He was trying to help me get going with my 820.

Barry: A few things:

1. Do you have an external watt meter in line? If so, suggest you try final loading step using the external wattmeter and leave the TS820 meter in Ip position. After you tune tank to resonance in Tune Mode by dipping the plate current (adjusting Plate Tuning capacitor for minimum Ip reading) then place mode switch in CW and alternately adjust Plate Loading cap and Plate Tuning cap for maximum RF output on the watt meter (approx 100 watts) without exceeding approx 200ma Ip. With practice you can do this in a matter of seconds.

2. Suggest you download a copy of Ken Kempski K4EAA loading instructions as they are a little more clear than what is in your TS-820 operating manual.

3. Just dont use the RF detector meter position. In lieu of that do what I suggest in 1 above.

4. Dont be afraid to give yourself some good ALC indication to work with when you are peaking the Drive control. Open up the Carrier Level control to get something around 2/3 to 3/4 full scale meter deflection. What you are doing is tuning the Driver stage tuned circuits to resonance and not trying to set some grid current level. You cannot hurt the finals if you run the Car Level Pot up to get a good ALC indication for peaking the Drive control. It is normal for that ALC indication to fall off as you pick up load current (Ip)as the rig has negative feedback to prevent oscillation and it will cut back the drive and reduce ALC indication as you get closer to 200 ma. DO NOT look at ALC after peaking the Drive control. No reason to go back and look at it and adjust it. Just monitor Ip as you load to max rf output on your watt meter. If no watt meter you will have to use the internal RF sniffer. Just make sure you have the sensitivity pot on rear of rig turned up to get a good deflection to peak.

Subject: [TS-520_820_530_830] Thanks to All

Thanks to all for your words of encouragement. It is very touching to realize how many friends I have on this forum. I am lucky to be alive and to have found this group. I had multiple pulmonary embolism in both lungs. My family doctor of 40 years started me on Heparin and Coumadin.

I asked him about the new blood thinners and he just dismissed them as too expensive and that he had successfully administered Coumadin for years with many patients. I appreciate that he is comfortable with this 1950s protocol.

Well my cardiologist showed up late afternoon and is taking me off the Coumadin and starting me on Xarelto. Just took my first one.

So I am happy camper and looks like may get to go home tomorrow. Still no smoking gun found. Usually caused by deep vain thrombosis in legs but ultra sounds were negative and no signs of AFIB. So important thing now is to prevent recurrence as this is a killer.

So will take the exercise advice to heart literally and good advice from Jim regards the Xarelto.

Once again thanks to all of you.

I will be back once get this behind me. There are plenty of you to help each other keep these Kenwoods we all love running.

Got to go now and try to get the cover put back on this Spectrum Sigma Infusion Pump. I dont think it is caled correctly !!!

M y TS520 has a straight knob/shaft/plate tuning capacitor scheme with no gear drive. The only reduction drive is the main VFO tuning control.
Slight resistance to rotating the drive, loading and plate tuning is normal , maybe because of the shaft bearings on the capacitors themselves.

Chip,

  First..what rig do you have?

   The VAST majority of the hybrids have a kind of a gear reduction for the "PLATE" control and a rather straight forward shaft/chain drive arrangement for the "load" & "drive" controls.
The "plate" control can be "freed up" by partly disassembling the "reduction drive" It's packed with grease...and after that long a time of no operation...it turns into semi set concrete.

Subject: Re: [TS-520_820_530_830] Hospital

My post wasNOT meant as a joke...it WAS meant, as a "light-hearted" attempt to cheer up Terry. It wasobviously misinterpreted by AG3Y...I know full well about these things. I have spent most of my adult life(34 years) as a Firefighter/Paramedic, unfortunately...guess what.....some "other ham radio operator" was talking on his radio(mobile).... was NOT paying attention....could not SEE or HEAR the big fire engine...with it's lights and sirens going...ran through an intersection and hit right where I was sitting. So now, I have a plate and six screw holding my neck together, my right shoulder will NEVER be the same...I have limited function of my right arm.....and a back that will NEVER be right, spent a few months learning how to walk again.....I hobble around in the shape of the letter "V" and have to use a canes to even move from one room to the other. I was forced to retire...because as you always hear...about cell phones and, texting...how about "hams" "talking and driving."

Again, my prior post was HUMOR and, OBVIOUSLY...by some persons standards, NOT humorous. I have probably created a "fecal matter storm" and really don't care. So, I can cover all the bases: Apologies if I offended anyone in the slightest.

This is not a joke. Some years ago, I was hospitalized, and a friend brought in a two meter handheld for me to play with while I was recuperating. EVERY TIME I hit the transmit button, the monitor in my room would start BEEPING an alarm !

I had to be content just to listen to what was going on. Not fun !

Maybe things are a bit more immune to RF now days.

Barry: I forgot to mention there is a standard test used to put the Driver stage thru its paces that requires no Dummy Load or Antenna. I have posted it here several times in the past. Need to put it in the Files. Here is quick re-cap.

1. Power on, Heaters on, SG switch off
2. Mode switch CW
3. Meter ALC position
4. Drive Control 1200
5. Carrier Level pot 1200 or greater
6. VFO at mid travel approx 250
7. Flip to send, peak Drive control for maximum ALC meter indication.
8. Increase Car Level Pot for full scale deflection (FSD) on the meter. If meter pegs just back pot off to bring indication back on scale.

If Drive stage is good you should have FSD on meter with Car Level pot typically no greater than approx 1000 on all bands except 10 meters may require a little more say around 1200 to 1300.

The full scale ALC indication should stay there and not slowly drift off.

Return rig to Standby (REC) position. Let it rest a few minutes and move to next band. 12BY7A is running Class A and with rig keyed it will see full Ip reading (approx 30 ma) and will get pretty hot. So need to let it rest in between long key down times.

Repeat this test on all bands. The Drive control may not peak at 1200 so make sure you swing it each side of 1200 to locate the peak.

For any band that has no ALC indication even with CAR LEVEL pot full CW then need to troubleshoot. If there are bands with low ALC indication first thing to do is perform a Coil Pack alignment as described in your operating manual maintenance section.

When done doing this Driver stage test remember to turn SG switch back to on position.

After you tune tank to resonance in Tune Mode by dipping the plate current (adjusting Plate Tuning capacitor for minimum Ip reading) then place mode switch in CW and alternately adjust Plate Loading cap and Plate Tuning cap for maximum RF output on the watt meter (approx 100 watts) without exceeding approx 200ma Ip. With practice you can do this in a matter of seconds.
>
> 2. Suggest you download a copy of Ken Kempski K4EAA loading instructions as they are a

little more clear than what is in your TS-820 operating manual.
>
> 3. Just dont use the RF detector meter position. In lieu of that do what I suggest in 1 above.
>
> 4. Dont be afraid to give yourself some good ALC indication to work with when you are peaking the Drive control. Open up the Carrier Level control to get something around 2/3 to 3/4 full scale meter deflection. What you are doing is tuning the Driver stage tuned circuits to resonance and not trying to set some grid current level. You cannot hurt the finals if you run the Car Level Pot up to get a good ALC indication for peaking the Drive control. It is normal for that ALC indication to fall off as you pick up load current (Ip)as the rig has negative feedback to prevent oscillation and it will cut back the drive and reduce ALC indication as you get closer to 200 ma. DO NOT look at ALC after peaking the Drive control. No reason to go back and look at it and adjust it. Just monitor Ip as you load to max rf output on your watt meter. If no watt meter you will have to use the internal RF sniffer. Just make sure you have the sensitivity pot on rear of rig turned up to get a good deflection to peak.

Barry,

From what I can see...the ones marked with the frequency and "trio" appear to be factory. I can not say for sure...but the silver colored
ones MAY be the CB HACK. See if you can look at the top to the silver cased crystals to see if there is a frequency stamped on the top.
Or....tune up on the 10meter band...with a dummy load and frequency counter...and see if it is on the correct frequency...instead say..somewhere
in the 27Mhz band.

The crystals in your picture that read 15.895 & 22.895 are correct. Check them all however...but the ones of real interest are the ones for the 10meter band.....
they should be marked 36.895 37.395 37.995

> > Right now after reshooting DeOxIt, the Load is the smoothest and most easily turned, feeling closer to what I might expect. Then the Plate is the next smoothest, followed by the Drive which is the stiffest. None are as free as a radio volume switch, to give a comparison. Visually examining, everything appears to be straight line shafts leading to the "business end" of the caps etc. The Drive has that overhead rod with the chains leading to the caps. Disassembly of that scares the crap outta me as I doubt I'd get everything lined back up correctly again.

Hi Gang:

Home now and tired but going to be OK so we need to end this discussion and get back to our treasured Kenwoods.

One last thing. I am on Xarelto and not Coumidin thanks to a cardiologist intervention. Not yet sure if for life. I would like to hear Off List from anyone with Xarelto experience and/or Factor V Leiden clotting disorder.

So back to Hybrid talk and thanks again to all for your support. I wont soon forget you.

I am going to see what I can do possibly tomorrow since today we hope to get our family together for Father's Day. I also met some guys at the testing facility yesterday that I hope can help just to make sure I get all of these recommendations right. Thanks to everybody for always being so helpful.

Still praying for you, Terry, and glad to hear that good report that things are going well!

Barry

Here are screen shots that give you a feel of how the set up described in my earlier post will work . All of the ssb and cw receiving aids worked with my TS-530s except for the dsb noise blanker which was not effective with a 1hz IF , direct conversion type set up .

SSB screen shot: bandwidth set from about 200hz to 2.9khz

http://i237.photobucket.com/albums/ff91/rtaylor0361/Capturessb_zpsa16c402f.jpg

CW screen shot :

Bandwidth set from about 400hz to 1khz with a 850hz center frequency .

http://i237.photobucket.com/albums/ff91/rtaylor0361/Capturecw_zpsc87a22d2.jpg

I hid the waterfall display , but if you wanted it, its available .
It takes a lot of tinkering to get it the way you like it ,but in the end its worth the time and effort.

Thanks for your help everyone !!!

A little background. For 28 years I was in the used car biz with my Dad. Being #2 in the chain of command, I got the job of figuring out why the "trade ins" that were "perfect" when the last owner traded it, now don't function like it should.

Taking what the wife told me, what the husband told me, what I observed at their home, and what the radio is telling me now, I am deducing this has been mod'd and the last time it functioned correctly was when the modder took off the case cover to do his stuff to it.

I re-assmebled last night and now realize the VFO main and sub dials are not in sync. All knobs and dials are exactly where I found them, so they haven't been in sync for a long time. The fact the husband told me he never used it, also tells me after it was modded it didn't work at that time. The wife told me she bought it from friends who were "big hams", so my assumption is a "big ham" wouldn't hack this to a CB mod'd rig because of legality and possible loss of license. All this points to someone who didn't know anything other than CB type radios, which the husband showed me his set up which he still was quite proud of.

Results, it's screwed up but probably not fatally. I also see to get in and undo the mod is past my skills and any attempt by me will most likely accentuate the list of maladies this rig currently has. So I posted it online describing what was wrong etc, and Monday it gets shipped off to it's new home where hopefully it gets resurrected as it really is in nice shape.

Thanks again for your time and help and 73s,

Chip

Chip: I am sorry you decided to sell the rig. Of course respect your decision to do so. Buying a 35 to 40 year old radio that has most likely passed thru many hands is always subject to risk. Going to be very hard to find one that will not have some issues.

I thought about writing a buying guide but never got around to it. Best is always local purchase where you can ask the ham to demo it. Even then it is not fool proof as it may have intermittent conditions that dont manifest during the demo or less than forthright guy will mask.

So much easier if you are an experienced hybrid owner so you can sit at the controls and put it thru its paces before purchase.

Hamfest is good in one respect as you can see the physical and cosmetic condition, but most likely wont be able to do much more than possibly power on. Cosmetic condition is important to me and if the external has been well taken care of better chance that inside has been as well, but no guarantee. Unless you are in to full restoration avoid the rigs that have been beat. Dirty and rusty radios with missing knobs and feet are going to have operational issues as well. Of course at Hamfest it is truly caveat emptor and you will get the 3 foot 30 second guarantee!

After that then QTH, EHam, QRZ and Ebay are all about the same. Maybe Ebay is a little better as seller is concerned about his ratings. I suggest never buy from any of these sources without a very clear understanding of what your right of return is and what the cost will be for that. If no right of return then no purchase. Always get the guys phone number and call him. Talk man to man and ask him to level with you on rig history and problems. You can usually tell from this call if the guy is a straight shooter. Listen for buzz words ie worked last time I tried it, only use it on 80, etc.

If you can see the rig in person here are several tests I recommend including:

1. Turn on Marker on each band and set VFO to mid range and peak Drive control at 1200 and note the S-meter levels. Should be approx S9 on all bands with 10 meters being a little lower on the 520 rigs. This tells you RF and IF amps are working, AGC is working, and Coil Pack alignment is close.

2. Perform Driver stage test in CW mode with SG switch off on all bands. Should be able to get FSD ALC indication on all bands with Car Level Pot at around 1000 with exception of 10 meters on 520 rigs. This tells you that you have TIF signal, TX mixer signal, Driver tube output, RF input to control grids of the 6146 finals, ALC is working, and no bandswitch issues.

3. If the guy has a dummy load then good to load rig on all bands and see if can get approx 100 watts output with 200 to 225ma. This assumes you know how to load the radio. If not make the owner demonstrate this. This tells you the state of the Final Tubes, HV power supply good, PA cage good, and no bandswitch issues.

4. Get a hold of the bandswitch and rock it from side to side at a band position. Should be no dead play or free play. Should have good positive detent and snap over. If there is any play can bet nylon coupler is cracked at one or more of the set of grub screws. Doesnt mean no buy, just a bargaining chip.

5. I also get a hold of the VFO knob and see how much axial and radial play. Another bargaining chip.

6. Look into fan housing and see if there is a build up of dust. Indication rig has not been cleaned out on regular basis.

7. Are there scratches and marks on top of the cabinet. Indication that things have been stored on top of rig which not only makes the scratches, but also impedes cooling air flow. I never stack my gear or place auxiliary gear on top my cabinets.

8. Try to look down inside the slots over the PA cage and see if it looks like any kind of liquid spillage has occurred.

Of course could always find intermittent conditions later when you get rig home. These are often easy to address with molex connector cleaning and relay contact cleaning or replacement.

Probably other things to look for but these are good place to start. Of course cannot do any of this if cant see the rig in person.

Chip,

  Sorry to hear that the rig was "not as described."".....been there. To undo the CB HACK mod on the 520 series..is not for the faint of heart!
Terry..k9tw...gives good council(glad your back)....are you looking for another 520 series...or higher? The 820 series and the 530 & 830 can also
have the CB HACK aka "FREE BANDING" mod done to them...it is easier to detect it on the 530/830 vs the 820. Any questions...you know where
to find us

Thanks for your help everyone !!!

A little background. For 28 years I was in the used car biz with my Dad. Being #2 in the chain of command, I got the job of figuring out why the "trade ins" that were "perfect" when the last owner traded it, now don't function like it should.

Taking what the wife told me, what the husband told me, what I observed at their home, and what the radio is telling me now, I am deducing this has been mod'd and the last time it functioned correctly was when the modder took off the case cover to do his stuff to it.

I re-assmebled last night and now realize the VFO main and sub dials are not in sync. All knobs and dials are exactly where I found them, so they haven't been in sync for a long time. The fact the husband told me he never used it, also tells me after it was modded it didn't work at that time. The wife told me she bought it from friends who were "big hams", so my assumption is a "big ham" wouldn't hack this to a CB mod'd rig because of legality and possible loss of license. All this points to someone who didn't know anything other than CB type radios, which the husband showed me his set up which he still was quite proud of.

Hi Joe:

I would say no one should panic. You may get lucky and be able to restore to design quite easily. I have seen them as simple as just one Het Osc crystal to a complete hack/QRO abortion. Sometimes the hack is not only ill conceived but very poorly executed. Some people have very poor workmanship skills. I didnt know you could use a beaver to chew a hole in the back panel!

I have of course gotten the real dogs and spent many hours in discovery mode and not always sure I found everything they did. I generally no longer accept them for repair as cant bill all the hours.

Good thing is you are not alone and have this group to help you, but if you have reservations about your ability or lack sufficient test gear then selling and trying to recover some of your loss is smart way to go. Might even consider parting it out to recover you purchase price. It hurts to see this happen, but reality is if we have no one parting out those rigs that have reached end of life then makes it hard for rest of us to do restorations.

42874. Looking for the schematic for the 3-diode (1N34a?) RF probe

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-17 06:41:06 UTC
From: n9kdy
Topic: 42874 Message: 42874

Checked the archives first, then did a search of the message store, and found lots of mentions of a 3-diode RF probe. Can't seem to find a circuit to go with it, though. Is it much different than the one-diode stock version that N5ESE has to his name on the web?

Can't be too tricky, it's just an RF probe, fast (germanium?) diode to rectify the RF without loading the oscillator and such too heavily.

In an attempt to cure my stubborn TS-530S VOX problem (Anti-Vox has no effect, no matter what VOX Gain and VOX Delay settings are used unless the speaker is muted or headphones are used), I plan to dive into the AF Board to renew the 'lytics along the line.

Any hints about board removal? Obviously, connectors must be gently unplugged and screws removed, but what about the wires soldered on topside? The reason I am asking is that -- more than once -- I have gone to great pains to access wiring or remove components in unfamiliar radios only to learn later that there was an easy, painless way to accomplish the same task known to the experienced, but not to me.

Also, what are your views on completely recapping the 530 (or 830, for that matter, since I have one of those on the way, too)? Good practice? Unnecessary if symptoms of unpleasantness have not appeared? I already did the HV caps, but that was dead simple and quick.

Thanks, gurus.

Will,

/*"Is it much different than the one-diode stock version.."*/

The only difference is the RF probe has "3" diodes connected in series
verses the RF probe with only "1" diode. That's all there is to it.

Thanks, John. Yeah, I tried that with the internal speaker and an external one as well. No joy.

I have another TS-530S (in absolutely mint cosmetic condition with original, unblemished boxes) that works perfectly in VOX mode with the same microphone, so I know that's not an issue, either.

My cunning plan is to get the one with the VOX problem up to snuff (it's about an 8+ cosmetically with a couple of minor scratches on the covers - front panel is flawless) and sell it in order to cover the cost of the TS-830S I just bought. I got overly excited as a new hybrid junkie and bought three radios when I actually just need one. I'm keeping two, however.

I did the same thing with Drake TR-7s a few years ago.

greeting,
my display counter is dead ..
I test moddk: to pin 16 on Q10 to check the blanking, to one side of L4 the choke in the -6v line, to both sides of R10, the 220 ohm resistor carrying 12v to the 5.1v zener D1, and lastly to pin 16 of Q6 to check that the 5v was getting to the I.C.'s

But i have 12v on R10 - 5V to Q6 , i see schematic -24V but i have -7v ????? My frequency counter on kenwood not work i c'an't see my frequency .
So I'm looking for a X54-1540-00 block replacement.
But I have a Frequency watch external 0 to 50 mhz.
I would like to use it on the TS-830M .
For see my kenwood receive frequency and emition.
Sorry for my english i'am french in reunion island (indian ocean)
THK

Craig,

I mean no disrespect but you said and asked for advice for:

"/*Also, what are your views on completely recapping the 530 (or 830,
for*//*
*//*that matter, since I have one of those on the way, too)? Good*//*
*//*practice?*/ "

My advice to you is /*NO*//**//*don't do that*/! Many hams have been convinced by sellers of capacitor replacement kits and other hams that you should replace ALL capacitors at once. They hide behind or use the excuse, *"/the capacitors are old so they should be replaced plus it's good insurance for the future/."*, which is pure non-sense and very very poor troubleshooting and repair techniques!! You can easily end up with cracked/broken foil runs on the PC board! The foil runs on the PC board of the hybrids are very thin and easily cracked by desoldering and soldering heat. Again, I /*DO NOT*/ recommend following the misguided "shot gun" replace of all electrolytic capacitors at once concept!! The only time any component or components should be replaced, regardless of the component(s), is if proper troubleshooting techniques have been used and have identified a component or components that is/are bad.

Intuitively it would seem like good thing to replace all the electrolytics in a 40 year old radio same as replacing all the carbon resistors and changing all the active devices especially front end Mosfet who some believe degrade with ESD exposure.

In practice most of these changes are really feel good changes that do not produce any measurable performance improvements. Almost all will report quieter operation etc. Not everyone has a discriminating ear. Also how can you measure the effectiveness of preventing a failure that did not occur. In the PM world of passenger airplanes and nuclear power they do reliability based preventive maintenance and it is OK to let some components run to failure. That would be case of most electrolytics that do not cause any collateral damage if they fail.

All of these changes you need to weigh the risk vs the reward. Easy to pull molex pins off the boards and to lift PC foils. These old phenolic boards have poor plating and cant handle many desolder/resolder cycles. I now use a Hakko 808 which is salty for average ham, but makes desoldering childs play.

Be very careful replacing electrolytics in your hybrid. Make sure you re-install as you found the polarity was oriented. There are two or three places on the 530/830s where they are reverse polarity with positive on the ground foil. This is not a mistake. The silk screen and the schematic are wrong and the as built config is correct. Electrolytics are similar to diodes and cannot tolerate very much reverse polarity. If you are unsure look at the schematic to see if there is negative voltage being applied in the circuit. This may be done to back bias a detector diode or to bias a FET that requires negative bias voltage on the gate.

Replacing the HV and medium voltage filter caps and perhaps the 14vdc, 12vdc and 9vdc power supply electrolytics is OK but I personally would not wholesale change all of them.

Mike, thank you. That is precisely the kind of sensible advice I was after.

I had never heard anyone recommend this shotgun approach to recapping except, perhaps, electrolytics in older power supply sections and, of course, ancient wax paper caps in antique gear.

It seemed like a clever but perhaps specious marketing ploy (possibly well intentioned in some cases and certainly self serving) but it got me to wondering if there was something universally amiss in the supply of electrolytics installed in the Kenwood hybrids. I was suspicious in part because the widely accepted Kenwood hybrid guru, K4EAA, does NOT sell "a complete recap kit."

73 and thanks again,

Craig

I have posted a couple of times why you need two RF probes and how to select diodes for RF probes and where to use them in your hybrid and cautions about exceeding reverse voltage.

You need a single diode germanium probe and a 3 diode probe. Any brand single diode probe will work just fine.

The Heath kit PK-3 used 1N191 gold bonded point contact diodes. You can find them but salty around $5.00 each. You do not need gold bond diodes. You are going to be measuring RF voltage at the plate of the Driver tube and the control grids of the Finals with it. You will use the single diode probe for all other measurements such as Carrier Osc and Het Osc levels. Just make sure the coupling/blocking capacitor has at least 500wvdc.

Your 1N34s will be just fine and simply place 3 in series observing polarity. If you buy a PK-3 off Ebay you need to remove back cover and shine lite in and see how many diodes are in series as it was a builder option to install 1 or 3. I have seen them with only one diode and if you run TX Level Diagrams you will be replacing that diode!

What are your feelings about using an ESR meter to test caps in-circuit?

Also – would it be of value (no pun intended) to create and publish a list of measured, in-circuit ESR values for the major electrolytic caps in the various hybrids? Those who have ESR meters could then compare values of suspected bad caps to the values in the list while not risking any damage by unsoldering.

Again, great and logical advice. I had read elsewhere of the fragility of the circuit board traces -- another factor that was giving me pause since I like to leave a repaired device in as good or better shape than it was in when it arrived.

This, of course, brings me back to the inoperative Anti-VOX question. Has anyone troubleshot this problem at component level? Speaker and microphone wiring have been ruled out as culprits. Cleaning of the Anti-VOX pot has proven ineffectual as well.

Hey Terry.....welcome back!

I know how Chip feels/felt about the "hack." Looking at the procedure..of what you have to do to get some of those boards out..IS not for the faint of heart...especially...when we love these "older women," and don't want to treat them bad! When I first started..really looking into the "girls" some of them were...more than I had experience with....that's why I joined this board......so.....glad u r home...and feeling better. I wasn't trying to scare Chip...just giving a warning and my observation(s) about buying a possibly "new" rig...and stating you can always come here.

Hi Joe:

I would say no one should panic. You may get lucky and be able to restore to design quite easily. I have seen them as simple as just one Het Osc crystal to a complete hack/QRO abortion. Sometimes the hack is not only ill conceived but very poorly executed. Some people have very poor workmanship skills. I didnt know you could use a beaver to chew a hole in the back panel!

I have of course gotten the real dogs and spent many hours in discovery mode and not always sure I found everything they did. I generally no longer accept them for repair as cant bill all the hours.

Good thing is you are not alone and have this group to help you, but if you have reservations about your ability or lack sufficient test gear then selling and trying to recover some of your loss is smart way to go. Might even consider parting it out to recover you purchase price. It hurts to see this happen, but reality is if we have no one parting out those rigs that have reached end of life then makes it hard for rest of us to do restorations.

>
> Taking what the wife told me, what the husband told me, what I observed at their home, and what the radio is telling me now, I am deducing this has been mod'd and the last time it functioned correctly was when the modder took off the case cover to do his stuff to it.
>
> I re-assmebled last night and now realize the VFO main and sub dials are not in sync. All knobs and dials are exactly where I found them, so they haven't been in sync for a long time. The fact the husband told me he never used it, also tells me after it was modded it didn't work at that time. The wife told me she bought it from friends who were "big hams", so my assumption is a "big ham" wouldn't hack this to a CB mod'd rig because of legality and possible loss of license. All this points to someone who didn't know anything other than CB type radios, which the husband showed me his set up which he still was quite proud of.
>
> Results, it's screwed up but probably not fatally. I also see to get in and undo the mod is past my skills and any attempt by me will most likely accentuate the list of maladies this rig currently has. So I posted it online describing what was wrong etc, and Monday it gets shipped off to it's new home where hopefully it gets resurrected as it really is in nice shape.

Craig,

Many hybrid owners have replaced the HV filter capacitors without any evidence indicating they should be replaced. Most hybrid electrolytic capacitors do not need replacing. Unfortunately there are hams who will replace them using the same concept, "they're old and it's good insurance for the future".

Another myth that some hams believe in which is similar but different, is that new high power amplifier tubes such as the 4-400, 3-500Z, and the 4-1000 for example, must be run on filament power ONLY for hours and hours before putting the tube(s) into service. One ham I had a discussion about this with, said the tubes, either in a brand new amp right out of the box or brand new tubes out of the boxes that are put in an older amp, have to be "FIRST" run for 18 hours straight on filament voltage ONLY before putting the tube in service. The "belief" behind this myth is the filament heat, over the many hours of idling, will eliminate any gas that has accumulated in the tubes. That's simply NOT true!! The filaments in these tubes do NOT absorb gas, the Zirconium coating that appears as a dull dusty gray color of the Anode (Plate) does! The filaments in these tubes are NOT coated with a gas absorbing coating and the filaments cannot and will not heat the Zirconium coating on the tube's Anode (Plate) to the temperature required to absorb any gas in the tube! The only way to heat the Zirconium coating on the tube's Anode to the high temperature required to absorb gas in the tube(s) is to have current flowing in the tube that heats the Anode to the high temperature and that can ONLY occur when current is flowing from the Filament to the Anode, normal operation, resulting in a dull Red glow on the anode during normal transmit operation (dull Red glow disappears in standby or when no RF is applied to the amplifier tubes which is normal). Unfortunately, there are many hams that, when they see the dull Red glow on the Anode's of these tubes, do the WRONG thing, they reduce drive until the Red glow on the Anode disappears. They believe the dull Red glow during normal amplifier operation, indicates the tubes are being over driven which is simply NOT true. There are times when over driving the tubes warrants drive reduction but under normal operation with normal drive and the dull Red glow appearing on the Anodes, that's perfectly fine. Those tubes are designed to operate that way.

Having said that, low power tube such as 6146, 2E26, sweep tubes, and receiving tubes should NEVER show any color on their Anodes. Any color shown on these tubes is a sign of a circuit or tube problem and the equipment should be shut down until the problem is found and fixed, and that includes the Kenwood hybrids.

Louis and others,

To prevent any stray capacitance from the circuit and/or adjacent components and wiring affecting the test results, at least one lead of the capacitor should be disconnected from the circuit and that includes any voltage equalizing resistors should be disconnected from the capacitor. I would not try to test a capacitor that's still connected in the circuit, too many variables that can affect the test results.

Not all capacitors have the same leakage rating. It depends on the capacitance value and voltage rating. For example, Sprague says capacitors that fall within the 1 to 100VDC rating have different leakage current ratings depending on the capacitance value of the capacitor. For example, a 2ufd capacitor and a 100ufd capacitor that are within this voltage range will have .31ma for the 2ufd capacitor but 1.3ma for the 100ufd capacitor.

Sprague also states that any capacitor value that is less than 75% of its capacitance value should be replaced.

There also is the "80/20" rule which means a capacitor may be replaced with a different capacitor with a value that does not exceed 80% of or less than 20% of the original value. I personally would not follow that rule that close, especially if the new capacitor value is more than 20% of the original capacitance value. Remember, "I" (current) leads "E" (voltage" in capacitors. That's part of the phrase, "ELI the ICE man" where "I" (current) lead "E" (voltage) in the "C" capacitor! When a capacitor initially starts to charge, the "I" current is at "maximum" and the "E" voltage is at "minimum". A "thump" is heard quite often in power supplies when they are first turned ON which is the high current surge in the capacitor when power is first applied to the capacitor.

Just wanted to make sure there weren't any caveats (the possibility of a resistor or a cap across each diode to do some current balancing or limiting, for instance) that I couldn't imagine being needed in my own head. I already have the thing about ready to shoe-horn into a Sharpie pen body, before I thought to ask.

There are often things in the universe that have not been dreamt of in my philosophy.

Plus, I've found it hurts a lot less to ask for clarification than it does to pick bits of semiconductor or dielectric out of my teeth because of something I didn't know (but could have asked about).

(BTW, I'm putting in a mini-slide-switch to 'jump out' two of the diodes and make it switch-selectable (one or three diodes), so as not to NEED two separate probes.)

How do you get on the leads of the electrolytic caps that are mounted flush to the boards as the majority our? I use the Blue Anatek ESR meter and it takes some experience to tell what is an acceptable ESR. We generally do not have access to factory data sheets that list ESR values for the original Kenwood caps.

I have developed some rules of thumb, but frankly havent found it a very useful tool for hybrid troubleshooting. I do measure and record ESR values for the ones I do replace.

Most service shops that have a ESR meter on the bench also have a nice supply of factory fresh electrolytics across broad capacitance and voltage ranges to use for comparisons and when in doubt they just replace.

Not trying to rain on your idea I just dont know how to get on the leads of most of the caps to run the test and good/bad is a bit subjective.

Almost all will report quieter operation etc. Not everyone has a discriminating ear. Also how can you measure the effectiveness of preventing a failure that did not occur. In the PM world of passenger airplanes and nuclear power they do reliability based preventive maintenance and it is OK to let some components run to failure. That would be case of most electrolytics that do not cause any collateral damage if they fail.

Hi Mike:

Louis was talking about using an ESR meter to test the electrolytics. With an ESR meter you are not measuring capacitance or leakage current. 99% of all caps can be measured directly in circuit with an ESR meter. No need to lift any leads. Just need to make sure the cap is discharged. About only exception is when a large cap is paralleled with a small cap and then need to lift one leg.

ESR meters work be applying low level AC signal (maybe 5mv to 20 mv) at around 100 to 200 khz in short pulses. Only about 4 circuit combinations you will encounter.
1. Parallel inductors such as chokes, coils and transformers and the XL is such that ESR meter doesnt see them.
2. Parallel resistors. The input Z of the ESR meter is very low maybe around 1 to 2 ohms so not bothered by the resistors
3. The junctions of transistors. The input signal level is too low to forward bias diodes or transistors
4. Parallel capacitor. Need to lift one lead

If you use a Capacitor bridge an/or Leakage tester the cap can check good, but still have higher than normal ESR. It acts like a cap with a high value of R in series with it.

Very easy to find Open or dried out caps as ESR will approach infinity.

Biggest problem is what is too high an ESR? What was original factory ESR?

Usually rule of thumb is anything over 10 ohms is too high and should be replaced. If the cap is in a switching circuit then anything over 0.5 ohms is probably too high.

Now what about those that read in circuit between 1 ohm and 10 ohms. This is where you need lots of experience and best if you can practice on known bad caps.

I always save any pulled cap for future use as reference.

ESR meter is nice addition to the bench but in my experience no sub for replacing whenever in doubt. Just not easy to get on the leads to test in circuit. For most must remove the board to access the foil side. ESR meter is also good low ohms meter to check contact resistance however it does not push any current thru a contact.

Certainly the board-mounted caps would be a challenge. I'm thinking that mainly the large capacitors that are easy to access would be candidates for this approach.

Those who have ESR meters could make it a point (next time they have the cover off the rig) to measure the easily accessible capacitors and post the values here. After a few posts for each type of rig, we'd have some indication of what is "normal". While these values wouldn't necessarily be the same as those of new caps, the measurements would be useful as guidelines for what is known to be within working range. For example, if 5 people measure a particular cap as having an ESR of 3 to 6 ohms, then there's a pretty good chance that if someone runs into the same cap in their rig showing an ESR of 15 ohms, it's a bad cap.

I'd be willing to collect the posted values into a table and store it in the files section of the group for reference.

Well there is the problem, silly me. Yes, the search facility for Wahoo
is what the youngsters here call "teh SuX0rs." Idiotic way to say it,
but I can agree in general.

Part of it, however, is how things are labeled in their database, which
is -another- can of worms. Having had to work around it before I think
the way I tagged it should show up fairly quickly from here on out.

The big issue? I spent more time checking the files, links, photos, and
database, and other such addendae (found all sorts of manuals, and a
bunch of broken links....) for a gif, tiff, or even pdf of jpeg of the
schematic in there, when I should have dug deeper in the messages for
text regarding it instead.

So, now in the "Files" area there IS, under "files," quite easily found,
a GIF file of the Heathkit PK-3A 3-diode RF probe. Problem solved.

Send whomever the next sod turns out to be to that schematic file, and
Bob's your Uncle.

You can download for free an entire 224 page book on probes from the following website:

http://www.tubebooks.org/technical_books_online.htm

Good Luck!

Robert

Ok my response was based on the discussion on the merits of a complete electrolytic recap. I thought you were talking about using the ESR to decide which of this total population to replace. Not very many caps that have accessible leads, but it would be nice to have good/bad ESR readings for those. Many of those you can also see the vent caps and get a good clue there is bulging or leaky.

Here are my logged results for the 900vdc B+ supply filter caps in a TS-830:

1. In circuit with bleeder resistors and small rf bypass caps in parallel. ESR = 0.33 to 0.35 ohms (new K4EAA caps)

2. Bad cap out of circuit with bleeder and bypass caps lifted. ESR = 1.00 to 1.20 ohms

3. New replacement caps from Ken K4EAA prior to install with no bleeders or bypass caps installed. ESR = 0.53 to 0.57 ohms

This is with a Blue Anatek ESR Meter

These old phenolic boards have poor plating and cant handle many desolder/resolder cycles. I now use a Hakko 808 which is salty for average ham, but makes desoldering childs play.
> >
> > Be very careful replacing electrolytics in your hybrid. Make sure you re-install as you found the polarity was oriented. There are two or three places on the 530/830s where they are reverse polarity with positive on the ground foil. This is not a mistake. The silk screen and the schematic are wrong and the as built config is correct. Electrolytics are similar to diodes and cannot tolerate very much reverse polarity. If you are unsure look at the schematic to see if there is negative voltage being applied in the circuit. This may be done to back bias a detector diode or to bias a FET that requires negative bias voltage on the gate.

Thanks Terry. This is helpful information.

I have the same Blue Anatek ESR Meter. Next time I have my TS-530S open, I'll measure the accessible caps and report here.

That happens to be in my bookmark file, couple of years now I think. I particularly like the oscilloscope books, just about the probe book. Great site. Fantastic resource for tube-jockeys.

42909. Topic Change - ESR Meters and other test instruments

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-18 02:30:32 UTC

Topic: 42877 Message: 42909

TS530 measurements and all..... I can't seem to find any available used, not even on ePay, that aren't MORE than the un-assembled kit from the supplier. I'm not stuck on Anatek brand, nor any particular name or make, but I am interested in getting an ESR meter some one of these days.

RETIRED GEEK HERE - Price is most DEFINITELY an object!

Saving some shekels here or there makes a big difference to us. That's why I'm fixing a mangled hybrid radio in the first place. But I've been spoiled over the years for decent tools. I would rather wait and save for a -good- one that I'll never need to replace instead of getting a "good enough to get going on" item and having to buy it three or four times.

(Craftsman and Snap-On hand tools? Of course. Buy it right the first time, and you only have to buy it ONCE.)

Before the ESR meter, I'll be getting an antenna analyzer box (when I can afford it) to get this trapped-coax attic dipole tuned up and connected to the TS520. Before THAT, though, I need to get a decent O-scope. The one I have I got for free, and it has been worth every cent....

Oh, I can't complain, it was free for the taking. But it's getting to the point where I am not sure I can keep it going any longer, so it's time for a replacement that I actually sink cash into.

At which point the "Buy it once" philosophy, beaten into me with a leather belt by my father, kicks in and I want to get -one- that will keep going for as long as I do. Single-trace, dual-trace, DTT, PC-based, whatever.

Perhaps there ought to be a semi-permanent topic for test instruments, where to find them, or to let others know when one or another person runs across a cache of say, VTVM's; which ones to avoid, which ones can be refurbished and which cannot without flaming-hoop hopping, and so on. Nothing in serious detail, just information that can be mined out of the archives.

Opinions? (And anyone know of a decent O-scope in need of repair and a home?)

HI Terry and Louis,

I don't ownan ESR meter so my response was based on the Sprague TO-4 capacitor checker I use, it does a nice job even though it's old technology.

If caps can be checked in the circuit with an ESR meter then that's fine with me. I guess I'll have to geta simple one and dosome experimenting/learning.

Craig:

1. What happens if you remove the Mic?

2. What happens if you remove the Mic, set mic gain to 1200, rig in SSB mode and flip to send? Any RF output?

3. Do you have normal side tone? Normal semi break in CW operations? Side tone is not enabled in SSB mode?

4. Perhaps a TS-530 owner that has normal VOX operation could measure the dc voltage levels at TP-2 on audio board for you.

If I get time I will measure TP-2 dc voltages on a TS-830 for you as the VOX amp and VOX delay circuits are similar. They both sample the audio amp output and rectify it and develop a dc control voltage that is used to counter the DC voltage developed by the VOX amp which ends up being input for an emitter coupled schmitt trigger circuit to key the relay.

Craig: If you have another functional TS-530 troubleshooting this should be a piece of cake! Go to TP-2 on Audio board and measure dc voltages there in VOX mode using same mic, same mic gain setting, same vox gain and anti-vox pot settings, same AF gain setting.

Not very many caps that have accessible leads, but it would be nice to have good/bad ESR readings for those. Many of those you can also see the vent caps and get a good clue there is bulging or leaky.

Almost all will report quieter operation etc. Not everyone has a discriminating ear. Also how can you measure the effectiveness of preventing a failure that did not occur. In the PM world of passenger airplanes and nuclear power they do reliability based preventive maintenance and it is OK to let some components run to failure. That would be case of most electrolytics that do not cause any collateral damage if they fail.
> > >
> > > All of these changes you need to weigh the risk vs the reward. Easy to pull molex pins off the boards and to lift PC foils. These old phenolic boards have poor plating and cant handle many desolder/resolder cycles. I now use a Hakko 808 which is salty for average ham, but makes desoldering childs play.
> > >
> > > Be very careful replacing electrolytics in your hybrid. Make sure you re-install as you found the polarity was oriented. There are two or three places on the 530/830s where they are reverse polarity with positive on the ground foil. This is not a mistake. The silk screen and the schematic are wrong and the as built config is correct. Electrolytics are similar to diodes and cannot tolerate very much reverse polarity. If you are unsure look at the schematic to see if there is negative voltage being applied in the circuit. This may be done to back bias a detector diode or to bias a FET that requires negative bias voltage on the gate.

Hi Terry:

1. The VOX does not trip - in other words, all is normal.

2. No RF output in SSB / Send mode with mic detached.

3. Side tone is normal. Semi break-in CW is normal.

Actually, I have purchased a TS-830S which will arrive tomorrow. I will take voltages measurements on it to compare.

I'll keep you posted.

Many thanks and 73,

Craig
W3CRR

Right-oh, Terry. Unfortunately, the fully functioning TS-530S is
located at another QTH temporarily. When we are reunited, I will do as
you suggested.

Thanks again,

Craig

Mike:

I always wanted a Tel-O-Mike especially for leakage measurements and of course you are correct for any capacitance bridge that I am aware of you need to lift one lead in circuit. I have a real nice Heath IT-28 that I keep for sentimental reasons but not much use anymore.

As I mentioned not uncommon to use the bridge to measure the capacitance value and it will be well within 80/20 tolerance and leakage will be low yet ESR will be high. Prior to ESR we would never have replaced a cap like that measured by a Tel-O-Mike or IT-28.

Not having to lift one end of most caps in circuit to test with ESR meter is a big plus. I think I paid $79.95 for the Blue ESR meter (digital). There is also a good analog unit available.

As I noted an ESR meter is not the magic pill. Still have to learn to recognize when ESR is too high and for about 90% of caps in the hybrids cant get on the leads from component side of board to test them.

Just my experience using one. I hear fellows on the Hybrid net talk about how handy has been testing caps in their hybrids and I sure would like to know how they are doing it.

Terry,

I use my nice IT-28 to find out the capacitance of small capacitors I cannot read the writing on!

Mike:

I always wanted a Tel-O-Mike especially for leakage measurements and of course you are correct for any capacitance bridge that I am aware of you need to lift one lead in circuit. I have a real nice Heath IT-28 that I keep for sentimental reasons but not much use anymore.

As I mentioned not uncommon to use the bridge to measure the capacitance value and it will be well within 80/20 tolerance and leakage will be low yet ESR will be high. Prior to ESR we would never have replaced a cap like that measured by a Tel-O-Mike or IT-28.

Not having to lift one end of most caps in circuit to test with ESR meter is a big plus. I think I paid $79.95 for the Blue ESR meter (digital). There is also a good analog unit available.

As I noted an ESR meter is not the magic pill. Still have to learn to recognize when ESR is too high and for about 90% of caps in the hybrids cant get on the leads from component side of board to test them.

Just my experience using one. I hear fellows on the Hybrid net talk about how handy has been testing caps in their hybrids and I sure would like to know how they are doing it.

Reminds me of the old times, when the only way was to use a known value of coil with the unknown capacitor, connect them, use the dip meter to find resonance and figure backwards to solve for C. (Or likewise solve for L with a known value of C, when the coil was the unknown....)

Whatever works, I guess.

Looks like I would do best at this point to get a better grid-dipper. One of the FET ones, likely can be found cheap. What I've got left is dying more rapidly every time I drag the poor antique critter out, and I don't want to muck about trying to resurrect yet ANOTHER dinosaur. Particularly true when newer types of instruments can give much better results anyway. Doing things the old, hard way isn't particularly a huge fascination with me, unless it's the only way I can afford to do it at all.

Tubes for the GDO I have are getting to be made out of unobtanium, and the price for a 6CW4 tube (it's a Lafayette TE-57) are getting to the stupid point. (I only have three coils for this old beast, too. Can't seem to get the give-a-crap to hand-wind more until I need them for something specific.)

I have 2 Heathkit GDO. A GD-1b, and a HM-1250. The HM-1250 is solid state and does not work as well as the GD-1B. The GD-1b does work on all bands but is marginal on the highest.

I have Millen GDO also. It's good on all but the highest band. The highest band does not work at all.

I also have an EICO 710. It's OK.

I would stay away from solid state GDOs. Besides they don't have a GRID!

IGNORE THE HEATHKIT TUNNEL DIPPER!

Bob: Yes that would be a good use for it. I use to do that as well, but now have B&K 875B digital LCR meter and the AADE IIB digital LC bridge. So can read values of chokes and caps pretty close.

In old days used my Millen GDO with a standard capacitor or inductor and would dip and calculate. Have also done this with Rf sig gen and O-scope and sweep and read frequency and then calculate. Lots of ways to skin a cat, but the digital bridges work so nice and more accurate.

I dont home brew much anymore so not making any gimmick caps anymore and will rewind hybrid plate chokes from time to time so get limited use out of LCR bridges these days.

I have seen some very cheap LCR bridges from China listed on Ebay and read some reviews and they get high marks. You might want to look in to one of those.

Bob:

You are correct the Tunnel Dipper just doesnt have enough "horse power". I am a Heath fan but sold mine very shortly after buying it.

I have the old standard Millen 90651 and the Measurements 59B. The Measurements is a big but a real joy to use. I got it for $60.00 at Dayton last year. I have never used the Millen 90652 solid state (FET based) and always wanted one, but they go pretty high when they come up on Ebay.

Kenwood makes a nice looking GDO that includes socket to test crystals but I havent used it either. Had the EICO 710 many years ago.

GDO is nice for testing antenna traps or making homebrew traps. Again RF sig gen and O-scope also works well.

If you have TS-430 or rig like that you can unlock it and use low level RF (2 to 3 watts) and run the VFO thru its range to sweep a trap or choke and use a light bulb to detect resonance.

About the only time I use my GDO these days is to test hybrid plate chokes and to check the series resonant holes after a rewind.

It was a must have instrument in old days when homebrewing.

Mike:

Not sure I would highly recommend you get a ESR meter. I know you run Drake and Heath gear and do some boat anchor work. If I did a lot of boat anchor transmitter and receiver work where there is point to point wiring and axial lead electrolytic caps mounted on terminal strips then a ESR meter would put your Tel-O-Mike pretty much in to retirement.

For work on radial lead PC board mounted caps not sure how you can routinely and easily access the leads to use the Tel-O-mike or a ESR meter. Back in the AM/FM tube radio days and the tube TV chassis days the Tel-O-Mike or IT-28 was nice to have.

I dont smoke, hunt, fish, gamble so I choose to spend my discretionary income on ham radio and test gear. More so on upgrading test bench in last several years. Test gear is the electronic techs equivalent of the Mechanics tools. I use to wrench some when three boys were home so have lots of specialized tools that seldom use these days but sure nice to have when you have the need.

Hi Mike:

On reflection I think we need to clarify to all members following this thread that we are talking about testing electrolytic capacitors here and not bypass or interstage coupling capacitors. For electrolytics the ESR meter is superior to the Tel-o-mike or IT-28 as normally do not need to lift lead to test in circuit.

Now for non-electrolytics capacitors as Mike pointed out the best way to test them is to lift one lead and test for Ua leakage current at the DC operating voltage. This is especially true for tube radios where very little capacitor leakage current can greatly affect operating bias.

If you do not have a capacitor tester like a Tel-o-Mike of IT-28 you can use a DC power supply, a Variac, and VTVM. You look for the quick meter deflection and then count the RC time constants back to zero. Usually 8 time constants is sufficient. The voltage at that point can be used to calculate the leakage current.

Sprague has a set of formulas for acceptable leakage current and the one I use to determine the maximum leakage current is: The square root of the applied dc voltage X the capacitance value divided by 2.

So just wanted to make sure it was clear that we are talking two different types and applications of capacitors. Use the ESR for in circuit testing of electrolytic capacitors and Tel-o-Mike, IT-28, or Variable Dc power supply and VTVM for bypass and coupling caps.

Terry,

In addition to the IT-28 I also have a IB-2A LRC bridge and a QM-1 Q-Meter. I use the Q-Meter when making coils and building tanks circuit. But there are time the GDO is more convenient.

I use the Millen GDO with a Millen antenna bridge to prune antennas.

But I too am slowing down on home brewing.

Bob: Yes that would be a good use for it. I use to do that as well, but now have B&K 875B digital LCR meter and the AADE IIB digital LC bridge. So can read values of chokes and caps pretty close.

In old days used my Millen GDO with a standard capacitor or inductor and would dip and calculate. Have also done this with Rf sig gen and O-scope and sweep and read frequency and then calculate. Lots of ways to skin a cat, but the digital bridges work so nice and more accurate.

I dont home brew much anymore so not making any gimmick caps anymore and will rewind hybrid plate chokes from time to time so get limited use out of LCR bridges these days.

I have seen some very cheap LCR bridges from China listed on Ebay and read some reviews and they get high marks. You might want to look in to one of those.

[Non-text portions of this message have been removed]

42926. PK-3 Schematic

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-18 14:14:59 UTC
From: Terry Wagoner
Topic: 42926 Message: 42926

The PK-3 schematic GIF in the files is missing the series scaling resistor. It shows two values. A 4.7meg for 11meg VTVM and a 3.9meg for 10meg DMMs. Need to insert either resistor depending on what meter you will be using. Insert it where they have listed the resistance values. Insert it in series with the "hot" lead going to the phone plug. It will then form a voltage divider with the input resistance of your meter so you dont have to divide readings by 1.414.

Without the series scaling resistor the probe wont read RMS values.

There are correct versions of the schematic on the web.

Bob:

I have seen the Heath Q meter in catalogs but never seen one up close or got to operate one. I remember reading about the special low inductance mica capacitor in it?

I think kind of the poor mans Boonton 160/260 Q meters. My guess is compares favorably.

Heath engineers had a knack for clever approaches to make serviceable test gear at price average hobbyist could afford. I can see where Q-meter really would come in handy for winding coils.

Amazing when you look at the size of these monsters in contrast to the modern digital LCR-Q meters of today.

Terry,

I grew up with this kind of equipment. When I was working for companies doing NASA/DOD work we used Heathkit equipment for general lab use and had HP, GR, or Boonton(the old one) instruments for final test.

The one thing Heathkit did not make in the 60's was good scope. In the 70's they made the IO-14 which is a knockoff of the Tek 561. If you could work with a single channel scope it was not bad. A lot od analog work was done with Tek 561s.

I now have a Heathkit IO-4235. Two channels, 35MHz. better than my Korean 35MHz scope. I can do a lot of work with it. I use a custom RF probe for looking at things over 35MHz.

I have a problem with limited space in my 20x20 Retirment Closet. So I keep the seldom used instruments in my storage unit(about 50 ft from my Retirment Closet).

I just bought a HP FET scope probe from eBay. $89. I could afford that (I THINK). Better than making one.

Subject: [TS-520_820_530_830] Re: Any TS-530S disassembly tips?

Bob:

I have seen the Heath Q meter in catalogs but never seen one up close or got to operate one. I remember reading about the special low inductance mica capacitor in it?

I think kind of the poor mans Boonton 160/260 Q meters. My guess is compares favorably.

Heath engineers had a knack for clever approaches to make serviceable test gear at price average hobbyist could afford. I can see where Q-meter really would come in handy for winding coils.

Amazing when you look at the size of these monsters in contrast to the modern digital LCR-Q meters of today.

[Non-text portions of this message have been removed]

42929. Inexpensive ESR meter

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

I agree with Terry.

For those who do not have an ESR meter, would like to experiment/learn how to use one, don't have a lot of cash to purchase a good quality ESR meter, there is a U.S. seller on eBay selling an inexpensive ESR meter for $19 (free shipping) under eBay ad #140988149020. This inexpensive ESR meter would serve as a good learning platform. I bought one of these last summer and it's easy to use. The meter operates on 9VDC making it ideal for field work. The meter could be easily installed in a plastic enclosure so it can be carried in your pocket for easy use at hamfest and swap meets. Just an idea for those who have considered purchasing an ESR meter but don't have a lot of disposable cash to spend. The ESR meter is fully assembled, tested, and ready for use as is but as I said, it would fit nicely inside a small plastic protective enclosure.

> Hi Mike:
>
> On reflection I think we need to clarify to all members following this thread that we are talking about testing electrolytic capacitors here and not bypass or interstage coupling capacitors. For electrolytics the ESR meter is superior to the Tel-o-mike or IT-28 as normally do not need to lift lead to test in circuit.
>
> Now for non-electrolytics capacitors as Mike pointed out the best way to test them is to lift one lead and test for Ua leakage current at the DC operating voltage. This is especially true for tube radios where very little capacitor leakage current can greatly affect operating bias.
>
> If you do not have a capacitor tester like a Tel-o-Mike of IT-28 you can use a DC power supply, a Variac, and VTVM. You look for the quick meter deflection and then count the RC time constants back to zero. Usually 8 time constants is sufficient. The voltage at that point can be used to calculate the leakage current.
>
> Sprague has a set of formulas for acceptable leakage current and the one I use to determine the maximum leakage current is: The square root of the applied dc voltage X the capacitance value divided by 2.
>
> So just wanted to make sure it was clear that we are talking two different types and applications of capacitors. Use the ESR for in circuit testing of electrolytic capacitors and Tel-o-Mike, IT-28, or Variable Dc power supply and VTVM for bypass and coupling caps.

> > Not sure I would highly recommend you get a ESR meter. I know you run Drake and Heath gear and do some boat anchor work. If I did a lot of boat anchor transmitter and receiver work where there is point to point wiring and axial lead electrolytic caps mounted on terminal strips then a ESR meter would put your Tel-O-Mike pretty much in to retirement.
> >
> > For work on radial lead PC board mounted caps not sure how you can routinely and easily access the leads to use the Tel-O-mike or a ESR meter. Back in the AM/FM tube radio days and the tube TV chassis days the Tel-O-Mike or IT-28 was nice to have.
> >
> > I dont smoke, hunt, fish, gamble so I choose to spend my discretionary income on ham radio and test gear. More so on upgrading test bench in last several years. Test gear is the electronic techs equivalent of the Mechanics tools. I use to wrench some when three boys were home so have lots of specialized tools that seldom use these days but sure nice to have when you have the need.

Bob:

I think O-scope and various scope probes probably least understood and most under utilized test gear on ham bench. Can be intimidating for some especially learning the triggering modes. You wont need this but if you are learning to use a scope look at all of Alan Wolke W2AEW scope tutorials on You Tube. They are first class. He is good instructor.

I dont have an "active" probe for my scopes. I think they result in about 100k input impedance up to about 10 mhz?

I dont use my scope that much as it is easier and faster to reach for the Boonton Millivolt meter, but glad I have it. I just got my first digital. Got the Rigol 1152E 100mhz and learning how to use it. I plan to take key waveforms in a TS-830 and store for future reference. A good winter project.

Terry,

I was an analog design engineer until the mid 70's I have a lot of experience with analog instruments especially scopes.

I came close to buying a Tek scope(HP does not make scopes) several years ago but after looking at the service manuals I decided not to. There chips in some of those scopes that are not available except from a donor.

What instruments you use depends on what you want to do.

I still design both digital and analog electronics. I only do the repairs on my ham radios that are necessary to keep them operational.

My next project is a CW keyer to connect between my computer and any of my HF transmitters. Why? For one thing the DX-60/HR-10 does not have sidetone. Several other boatanchors are the same way. This keyer will allow me to easily switch between the computer and one of the hand keys.

Recently I have been studying DDS VFOs. I don't think they are all they are cracked up to be. A PTO/heterodyne VFO is really a better solution than a DDS. But other than band switching it is not computer controllable. I have several Heathkit LMOs/VFOs to work with, Kenwood and Drake PTOs would also be a good choice.

With the problem of crystal ageing using a DDS for the heterodyne oscillator is a viable solution. That would allow me to have the xceiver remote except for the VFO. I do have an operational Kenwood VFO-520 and other Kenwood VFOs are common on eBay.

Why is a 79 year old retired EE doing stuff like this? It's something I can do to keep busy in this Retirement Closet. It keeps the brain busy.

Several years ago the ARRL published a couple of articles on making a spectrum analyzer. That's an unfinished project because of some parts I still need to buy. But I plan to finish it.

Do I really need a spectrum analyzer? Probably not. But it is an interesting project.

Subject: [TS-520_820_530_830] Re: Any TS-530S disassembly tips?

Bob:

I think O-scope and various scope probes probably least understood and most under utilized test gear on ham bench. Can be intimidating for some especially learning the triggering modes. You wont need this but if you are learning to use a scope look at all of Alan Wolke W2AEW scope tutorials on You Tube. They are first class. He is good instructor.

I dont have an "active" probe for my scopes. I think they result in about 100k input impedance up to about 10 mhz?

I dont use my scope that much as it is easier and faster to reach for the Boonton Millivolt meter, but glad I have it. I just got my first digital. Got the Rigol 1152E 100mhz and learning how to use it. I plan to take key waveforms in a TS-830 and store for future reference. A good winter project.

Bob:

I think it is great you are making best of limited space. Hams are pretty ingenious when it comes to this. I have literally seen small closet operating positions and card table service benches.

You should talk to Mike W5RKL about his DDS VFO experience. I think he resolved spurs and has a buffer amp to get the drive voltage he needs for tube rigs.

We have a similar approach to the hobby. I work hard to study and understand how all the circuits in these hybrids work. Havent mastered all of them yet and may never understand all the design basis, but it is fun for me. Light bulbs still come on all the time and I am 67 and been learning since around age 12. Learning is never ending and hopefully it can help stave off early dementia if you keep the mind exercised. No guarantee as genetics surely plays a factor.

Have fun.

>
> My next project is a CW keyer to connect between my computer and any of my HF transmitters. Why? For one thing the DX-60/HR-10 does not have sidetone. Several other boatanchors are the same way. This keyer will allow me to easily switch between the computer and one of the hand keys.
>
> Recently I have been studying DDS VFOs. I don't think they are all they are cracked up to be. A PTO/heterodyne VFO is really a better solution than a DDS. But other than band switching it is not computer controllable. I have several Heathkit LMOs/VFOs to work with, Kenwood and Drake PTOs would also be a good choice.

>
> With the problem of crystal ageing using a DDS for the heterodyne oscillator is a viable solution. That would allow me to have the xceiver remote except for the VFO. I do have an operational Kenwood VFO-520 and other Kenwood VFOs are common on eBay.

You wont need this but if you are learning to use a scope look at all of Alan Wolke W2AEW scope tutorials on You Tube. They are first class. He is good instructor.

The most important part to replace on a TS-530S is the coupler that connects the wafer switch in the finial cage to the band switch shaft .It should be replaced ASAP . These plastic couplers in the radio are no good , can slip , and result in rf damage to the wafer switches in your radio .If you find that the coupler in the finial cage is cracked ,don't use the transmitter again until this situation is fixed . While your at it , I would replace the coupler on the load control shaft also . Go to the K4EAA web site for more info and for the purchase of brass couplers that will last for ever.

http://www.k4eaa.com/examples.html

I am still using the original filter caps and they are doing fine but replacement is a good thing to do on a old radio .

If you look at the K4EAA site , you will find that their are some resistors in the finial cage that are rated so that if a person does something reckless in the tunning of the radio , these resistors will burn up and prevent a more costly repair . A look at those resistors in your radio to see their condition would be advised .

When putting the metal cabinet back together after work on the radio ,
be sure to put each screw in loosely so that the cabinet will have some wiggle room to line

up the holes . After all the screws are installed , you can then torque them down .

42935. Oh-oh! TS-830S glitches

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

In my new Kenwood hybrid frenzy, I have purchased a TS-830S as a companion to my two 530Ss (one that looks a little crappy but works perfectly and the other that is in absolute mint condition cosmetically but is dead on most bands).

The 830 arrived yesterday looking in pretty good shape overall, though showing signs of long term neglect. I dusted the radio out a bit and inspected for obvious damage. Then, fairly assured that a house fire and neighborhood blackout would not ensue, plugged 'er in and powered up. At first, the meter light failed to glow, but a light "rap" on the cabinet top brought it to life.

Well, I shut the radio off after ascertaining that operation was normal (120 watts out and good reception) on all but two bands -- 7 and 21 MHz. Here are the symptoms:

* on 7 MHz: normal reception but little transmitter output (maybe a couple of watts) unless I fiddle relentlessly with the the obvioously dirty and/or misaligned and/or damaged band switch. ALSO (interestingly) the digital display intermittently shows a "0" preceding the "7.xxx".

* on 21 MHz: normal reception but --- okay, same as 40 meters on transmit.

* A very low level "buzzing" is heard when tuning up. This is not apparent on my TS-530S.

After taking the necessary HV safety precautions (I'm an old timer for a reason) , I cleaned the PA cage (somewhat dusty including, of course, the 6146Bs), lubed the fan and treated the PA portion of the band switch with DeoxIT. I also inspected the band switch coupler. It looks fine -- no cracks (though I do plan to replace it with one of Ken's brass do-dads).

The symptoms remain.

I will, of course, go through the entire radio cleaning plug-in board contacts, the rest of the band switch, the pots, etc. but I'm wondering if the commonality of symptoms on 40 and 15 meters points to a particular area. I'm also wondering why I get a couple of watts of output when the band switch fails to make proper contaxct on those bands AND, what's with the intermittent "0" digit display on 40 meters?

Thanks and 73,

Craig
W3CRR

42936. A bfo no no on the TS-530S !

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-19 11:05:58 UTC

Topic: 42936 Message: 42936

I noticed that during receive I was always adjusting my IF shift down about 200hz to get the the best receive effectiveness so one day I did as others have suggested and readjusted my bfo down so that the SSB low frequency cut off was about 200hz from around 400 hz . This turned out to be a bad idea because it also shifted the transmit spectrum down 200hz . Because there is a lot of energy in the low audio frequencies , shifting the transmit audio spectrum down makes the radios alc and audio compressor work harder and that's not a good thing if your goal is being herd and understood .I returned the bfo to its original position and now just use the IF shift to adjust my receive audio spectrum .

Craig:

I am a little busy now so will let other help you. Willing to help if I can. Couple of quick observations:

1. You mention 120 watts output. If that is into dummy load then suggest one of two things A. Loaded to approx 250 ma or more Ip OR B. Wattmeter is not caled. If into an antenna or a load that is greater than 1:0 to 1 VSWR then not taking reflected power in to account. OK to load to 250 to 260 ma when putting a new rig thru its paces, but not as a matter of routine as no reason to make finals dissipate that much heat. Most 830s will not typically load to 250 ma IP or more without power no longer increasing. Not a criticism just suggest you load to around 100 watts output without exceeding approx 225ma Ip as your normal practice. Receiving end wont notice difference between 100 watts and 120 watts. Tube longevity might.

2. What does Marker signal do on all bands including the low rf output bands? A well aligned TS-830 will get close to S9 on all bands at center of VFO range with Drive controlled peaked close to 1200.

3. Go to Operating manual Sect 6 and do a quick Coil Pack and IFT alignment using the Marker and S-meter and report back if any
improvement in weak TX. Remember you need Heaters on to peak the Drive coils.

4. I would also do the Driver Stage test that I have listed here several times. You do this in CW mode with SG switch off. Should be able to get FSD ALC indication with Car Level Pot no greater than 1200 and typically around 1000 to 1100 is sufficient. All bands should produce FSD and no gradual fall off. Let rig rest in between each band as Driver tube is running Class A at max IP and gets hot.

I have been ill and have couple of rigs here that I must attend to. Be glad to help if I can if you get stuck. There are some good 830 owners who can help you.

Hopefully you are not looking at bad bandswitch contacts on RF board.

Good Luck
Terry K9TW

One correction you may have to increase CAR Level pot to around 1300 to 1400 to get FSD ALC indication on 10 meters but typically can get full scale ALC on 10 meters with well aligned TS-830 with good Driver tube and spec tube dc voltages.

OK this is the last "one more"!

I forgot to mention if you can easily get 120 watts plus out of your new TS-830 suggest you take a look at the SG voltage on the finals and do a good visual on the Plate choke for signs of overheating (darkened windings maybe brown or even blackened). It is possible that someone did a QRO mod which most commonly increases the 6146 screen grid voltage. Always measure directly at the 6146 tube socket on the final board.

I obviously havent seen all TS-830s but 120 to 125 watts output in my experience is pushing the limit.

Thanks again, Terry,

The 120 watts out into a dummy load is loading to about 260 ma. I had planned to back off a bit in actual operation. By contrast, my 530S peaks neatly and correctly at about 225 ma with 100 to 105 watts out.

The 40 and 15 meter bands do come alive in transmission with judicious (and extensive) "wiggling" of the band switch -- which is why I suspect something more mechanical and electrical going on here.

This radio was owned most recently by one of our good guy forum buddies, so I doubt that it's had any hinky mods. It just seems to have been in storage for awhile.

OK Craig that is what I suspected you were doing for testing purposes only and not normal operating practice.

Before removing the vertical bandswitch boards suggest you contact Dick W0NTA about his bandswitch repair for loose rivets and contact fingers that have lost temper. He does not use the silver pen method that Ken K4EAA describes. Dick installs small gauge jumpers.

A good test is not to measure conductivity with an ohm meter or ESR meter as it does not push enough current. I use low voltage DC supply and do the standard 6vdc/1amp relay contact test on these contacts. A good contact will be in the 100mv to 50 mv range or better measured by a DMM across the contacts.

Biggest challenge is the desoldering of the vertical board pins that mate with the RF board. Dick and I use a Hakko 808 gun as we do enough hybrid work to justify the cost. Otherwise you are looking at a lot of solder wick and solder sucker work which can be a challenge.

Maybe deoxit and exercising will get you buy for awhile, but sounds like eventually you will have to undertake this repair.

Craig,

A common issue with most of the Hybird radios is the wafer switches on the RF board. Still do the service alignment as Terry suggested. Once you have done that and if there is no noticable difference then I'd give the wafer switches a good clean with DeOxit and a good blow out with canned air. Then have a look at each wafer switch in each band position ensuring the little brass fingers are actually making contact with the wiper, of course this is done with the rig turned off and HV discharged. If the fingers aren't contacting then it's a matter of just pushing back with a long enough tool, but be gentle as they are thin.

Thanks, Dave,

Yes, as we all expected, the RF Board wafers were the culprits. All bands are now operative. One DeoxIT treatment brought back a semblence of life with intermittent dropouts. A second application seems to have had more positive and consistent results. I am tempted to remove the RF Board and a give the wafers a more thorough treatment by removing them, cleaning mechanically and electrically securing the rivets to the copper. As I said, I am tempted -- but not moved (for the moment, anyway).

One anomaly remains, and that is the mysterious and intermittent appearance of a leading "0" on the 1.5, 3.0 and 8 MHz bands. cleaning the plug-in headers on the display board had no effect.

I realize that a couple of hours of further contact cleaning and freshening are ahead of me. But, I'm a happy guy right now.

73 and thanks again,

Craig

Craig:

Are you saying the display is normal with the exception that it is displaying an additional leading Zero?

Yes - sometimes. The leading zero is intermittent and often disappears as the unit warms (indicating another connector problem, I would guess). I cleaned all the connectors on the counter board, but have not touched the PLL board, yet.

Ok I have not seen this. Counter needs Bandswitch position input and DCBA PLL divider input for proper display. If you are getting proper display plus the leading zero it would seem you are getting 9vdc from RF board to Conn 4. I will look at circuit and see if I can figure out what would cause display of the additional leading zero.

I also mispoke yesterday about contact resistance acceptance criteria. I got my relay contacts confused with my rotary switch contacts. Centralab catalog shows factory design contacts in the range of 2 milliohm to 15 milliohm as opposed to the 50 to 100 that I told you.

The reason I suggested using 6v/1A mv voltage drop testing over ohm meter testing was two fold. First not many hams have a milliohm meter and secondly it is important to get enough power thru the contact to penetrate any oxide film. Contacts will develop film from exposure to atmosphere especially if they sit idle and are not wiped frequently.

Centralab shows their phenolic and ceramic wafer switch contacts are brass alloy and silver alloy.

If your Deoxit fix is not long lived and you decide to install small jumpers make sure you dont overheat the contacts as can destroy the heat treated spring temper of the contact shoes. I install the jumper out at the window on the loop that is formed when the contact is bent and riveted. Clean this area good first to brite metal and I use a little liquid flux so solder wets quickly. I usually cut leads off 1/4 watt resistors to make the jumpers.

Looked at the TS-830 counter schematic and Counter Chip Q5 TC5070P and see that Pin 4 is the Leading Zero Blanking (LZB) pin. Looking at Toshiba data sheet reveals that LZB must be "L" to suppress the leading zero on 7, 3, and 1.8 mhz. So Pin 4 must be grounded.

Two possible problems: 1. Bad solder connection at Pin 4 and/or Bad ground connection at PC board ground plane foil hold down screws.

Can measure resistance from Pin 4 to chassis ground and see what you get. With rig off should be very low value. May go up in to low double digit resistance with power on?

Try backing off the two counter board mounting screws at the back corners of the board and re-snug them. If that does not work then will have to remove board and inspect Q5 soldering under magnification.

As I mentioned I have no 1st hand experience with leading zero suppression problems with the TS830 display, but as you suggest wont be surprised if bad ground connection isnt the problem. However would think it would also cause other erratic display issues as well?

I say we go to Champps and have waffle fries with sour cream.

Why? it sounds like a nice way to spend the afternoon.

At any rate, many thanks to Terry (again). I did a bit of hold down screw re-tightening last night to no avail, so, I may have to pull the board. I did notice that one of the counter board screws was a slotted head one -- quite unlike any others in the radio. Perhaps the original got stripped or...??

Oh - as i mentioned, I intend to do a thorough cleanup of the 830 this weekend and would like to pull the front panel to soak and get the grime off. . I don't have the radio in front of me (I'm at work and it's not) but it would appear that extracting the VFO is a necessary step. Is this so and, if so, what's involved? Anything tricky?

73,

Craig

Hello All,

I have just joined the group. My name is Jim and I make Kansas City my home. For some time, I've been active on 40 and 20 meters with QRP CW rigs.

I've just purchased a TS 520SE. It has problems, but nothing too serious. It's really been nice to learn about useful approaches to repair ... like Deoxit. I don't know what I would do without it!

So I'm mostly just "reading the mail" and learning a lot.

Best,

Jim

Looks like someone had counter board out and lost a screw as both rear screws are slotted head. No need to pull VFO just two screws at rear of board and two countersunk slotted head at top center of front sub panel. Board and display and mounting bracket will come out.

Well you could try grounding Q5 Pin 4 next time you have a leading zero displayed. Just make sure you are on Pin 4. I bought a set of SMT needle point probes for my DMM and has long sharp probe tip that is insulated with just the tip exposed. Really good for getting on chip pins without slipping off them.

Regards VFO removal you will want to do that at some point to clean the rotor shaft wiper contact at rear of air variable, re-snug the PC board screws, and to Tri-Flow the gear train. Just have to remove 4 allen head metric screws and gently pull VFO forward and slide the two silicon boot mounted lamps out of the U-slots on each side. Then unplug mini-molex connector from rear shield can. Just be careful re-installing the small shield can screws as easy to cross thread them and also easy to pinch the VFO dial lamp Red power leads when re-tightening the 4 allen heads. I have seen several with very flat leads. If VFO has never been removed allen heads will have locktite on them so good idea to work them back and forth as you loosen and remove them.

Jim:

Welcome to the group. Just use Deoxit sparingly on de-energized rig and dont let it pool and blow it off with canned air.

You de MAN! Thanks, Terry.

Say, regarding the Hakko 808 -- I'm tempted. Does it fit into relatively snug spaces? It looks to be about the size of an old Weller soldering gun.

Welcome to Jim in KC. I will be your Kenwood guru.

Oh, sure -- Terry and the Pirates will actually answer your queries, but I perform an equally valuable service. I will ask the questions that you are too embarrassed or ashamed to pose -- and I will lead the way in making dumb-ass mistakes (with full disclosure) thus saving you time and expense.

You're welcome,

Craig
W3CRR

Oh, by the way, Jim -- do you remember the old KY-102 FM radio station? My wife was part of the on-air "morning crew" there some years ago. She was also in charge of station promotions. I tease her for missing an terrific promo opportunity by not staging a "KY Jam and Jelly Making Contest."

Craig,

The barrel of the '808 is about the diameter of a "standard-sized" Weller soldering pencil, not a gun. I am at work so I can't measure mine but, from memory (bad source!), I think it is about 3/8" in diameter. It does get into close quarters. Since you only need one hand (no solder wick or solder sucker) it leaves the other hand free for manipulating and extricating desoldered parts.

I'm sure one of the '808 owners sitting at their bench can provide accurate information before I get home.

Hi Craig,
I've been following this thread.

We have a page up on our site about repairing the bandswitch, with a bunch of pictures. I've done quite a few of them now, and it seems to work fine.

http://www.hybridrestore.com/bandswitch-repair/

Several optional tips including skinny snout. They are a little salty.

I think Jimmy Lamanteer WB2KNR has bought additional tips for his. Might contact Dick W0NTA who does TS530 restorations and see what he uses. He has a website and he and Jimmmie phone numbers are listed on the Kenwood repair tech list that Mark Gilger put together. Terry

Hello All,

I have just joined the group. My name is Jim and I make Kansas City my
home. For some time, I've been active on 40 and 20 meters with QRP CW
rigs.

I've just purchased a TS 520SE. It has problems, but nothing too
serious. It's really been nice to learn about useful approaches to
repair ... like Deoxit. I don't know what I would do without it!

So I'm mostly just "reading the mail" and learning a lot.

Best,

Jim

42963. TS-830S minus zero

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-21 00:48:34 UTC
From: Craig Roberts
Topic: 42877 Message: 42963

Well, I replaced the non-matching Counter Board screws and the stray, leading "0" has vanished on the 160, 80 and 40 meter displays. Never mind that I re-tightend the original screws last night - twice. This time it worked (at least so far).
So, the 830S is now working perfectly normally, but I'm, still giving it a "bath" this weekend. It needs it.

Oh -- the cabinet /desperately /needs painting. Anyone had any luck going the Sherwin Williams auto-paint-store-color-matching-spray-can route?

73,

Craig

Good. If it comes back just pull the assembly and clean the ground plane foils in the mounting hole area and polish the mating chassis area. With bolt missing could have some corrosion/oxidation at that mounting hole and not getting good low resistance connection. Some folks install star lockwashers, but if areas are cleaned shouldnt have to do that.

Terry and Craig,

Have measure or should I say attempted to measure voltage on TP2 on audio board. No voltage being recorded at this time, however it switches the microphone on without throwing the relay. Using two tone with the MM probe on TP2 I get 125mV, but with no two tone, no voltage appears

TP3 RX 12v

TX 10.5v

Subject: [TS-520_820_530_830] Re: Any TS-530S disassembly tips?

Craig:

1. What happens if you remove the Mic?

2. What happens if you remove the Mic, set mic gain to 1200, rig in SSB mode and flip to send? Any RF output?

3. Do you have normal side tone? Normal semi break in CW operations? Side tone is not enabled in SSB mode?

4. Perhaps a TS-530 owner that has normal VOX operation could measure the dc voltage levels at TP-2 on audio board for you.

If I get time I will measure TP-2 dc voltages on a TS-830 for you as the VOX amp and VOX delay circuits are similar. They both sample the audio amp output and rectify it and develop a dc control voltage that is used to counter the DC voltage developed by the VOX amp which ends up being input for an emitter coupled schmitt trigger circuit to key the relay.

Did you try measuring the resistance at Pin 4 to chassis ground with the 0 displayed?

Measure for potential first (should be 0 or very low) and then measure the resistance. Then measure the resistance with rig down powered. Should be very low with rig down powered.

If 0 or very low potential at Pin 4 then temporarily ground it with jumper to chassis ground to see if 0 is blanked. If temporary grounding doesnt blank it then not likely you have a bad ground connection at Pin 4. Resoldering Pin 4 is not going to help if temporary ground jumper doesnt blank the 0.

I think finding replacement Q5 will not be easy and you will be looking at getting replacement counter board from Bob Mansker or elsewhere.

Welcome to the Group Jim! You will find much valuable information by just reading the posts, and of course asking questions as you get into the use and care of your TS-520SE. I have two hybrids-a TS-530SP and a TS-830S, and had several issues with them in the past that this forum, especially Terry and Mike, helped me to correct. Yes-and that can of Deoxit along with some canned air is an important tool. Welcome again to the group and to the enjoyment of Kenwood hybrids.

Hi All
I just received my shipment from Milestone Technogies
http://www.mtechnologies.com/tools/index.htm#alignset
First let me stay they do not pay me to advertise,so it's just my opinion
I ordered the 10 pc and the 3 pc set
The ten pc set would be a better choice Alignment Tool Set, ABS Plastic
The quality is good and shipping was more reasonable than Ebay
This time i will align my ts830 on it's side as putting it upside down i think makes me apply more force on the align tool,and then we end up with a slug at the bottom
Just a thought

Dave:

Thanks for attempting to measure voltages at TP-2 for Craig. I did not explain myself very well. What I was trying to confirm on a TS-530 that has a functioning VOX what the normal Anti-Vox DC "bias" or threshold voltage is.

I know what it is for a TS-830, but not for a 530 but suspect very close to same as circuits are essentially identical. The reason wanted to get this for Craig was so he could tell if his Anti-VOX circuit is working. Is it producing a DC threshold voltage when there is strong audio signal from Q6 Audio Power Amplifier being coupled to the speaker line ?

At TP-2 there can be two signals. Amplified Mic Audio (ac signal)either from the speaker or your voice and DC "bias" from the Anti-Vox circuit. The Anti-vox essentially establishes a DC threshold that the mic audio has to overcome in order to key the emitter coupled Schmitt trigger and key the relay. It does this by sampling the output of Q6 speaker line and full wave rectifying it.

Anti-vox circuit samples the Audio Power Amp Q6 output on the Speaker line and is coupled thru the wiper of the Anti-vox pot. It is amplified and then full wave rectified by Q7 and D6/D7. The output from the speaker is rectified and used as a kind of varying "bias" voltage for Anti-vox function based on level of output from Q6.

So the signal I wanted someone to measure was the DC voltage at TP-2 produced when there was no audio from Q6 and when there was a strong audio output tone from Q6 being coupled to the speaker line. I did not state that very well.

One way to do this is to use the Marker signal.

Here is how I measured this DC level at TP-2 in a TS-830:
1. Antenna on dummy load
2. RFG at "5" (need to get a no audio voltage level)
3. AFG at "2"
4. Mode LSB or USB
5. Vox Gain off
6. Anti-Vox at Full CW
7. VFO 200, Drive control 1200
8. Marker OFF
9. Measure DC voltage at TP-2 with DMM. Need to wait until voltage decays completely off. Should see +0.001 to -0.001 dcv bouncing back and forth. So essentially zero DC offset voltage at TP-2 with no signal conditions.
10. Now turn on Marker and tune VFO for approx 800hz note and peak Drive control. Watch the DMM and tune the VFO for maximum DC voltage. Should see something like + 0.0305 vdc. Just tune VFO and Drive control for maximum voltage.

When you turn off the Marker you will have to wait awhile for voltage to decay to lowest no audio signal level.

If Craigs Anti-VOX is not producing this 0.0305 vdc bias voltage then speaker sounds will produce sufficient signals to key the rig thru the mic. Cleaning and exercising the Anti-vox pot as suggested my Mike W5RKL would be first thing to try. If there is no power amp audio coming from the wiper of this pot then the Anti-vox circuit cannot produce the necessary bias or offset voltage. If cleaning pot doesnt produce 0.030 vdc at TP-2 then have to trouble shoot the Anti-vox circuit.

Another way to get a test tone out of Q6 Audio Amp would be to inject modulated RF into SO-239 from RF signal generator that has internal or external modulation capability, but suspect Marker test is as good as any.

Terry,

Have just tested both 530s. They are identical in all respects to this test procedure

TP2 0.005v at resting voltage

with marker on and tripping vox

TP2 0.0027 - 0.0031v

Previously used analogue micro volt MM, hence why it didn't respond to rapidly changing voltage.

Let me know anything else you need checked, heading to work in an hour and will be available tonight upon return

Dave:

Thanks for attempting to measure voltages at TP-2 for Craig. I did not explain myself very well. What I was trying to confirm on a TS-530 that has a functioning VOX what the normal Anti-Vox DC "bias" or threshold voltage is.

I know what it is for a TS-830, but not for a 530 but suspect very close to same as circuits are essentially identical. The reason wanted to get this for Craig was so he could tell if his Anti-VOX circuit is working. Is it producing a DC threshold voltage when there is strong audio signal from Q6 Audio Power Amplifier being coupled to the speaker line ?

At TP-2 there can be two signals. Amplified Mic Audio (ac signal)either from the speaker or your voice and DC "bias" from the Anti-Vox circuit. The Anti-vox essentially establishes a DC threshold that the mic audio has to overcome in order to key the emitter coupled Schmitt trigger and key the relay. It does this by sampling the output of Q6 speaker line and full wave rectifying it.

Anti-vox circuit samples the Audio Power Amp Q6 output on the Speaker line and is coupled thru the wiper of the Anti-vox pot. It is amplified and then full wave rectified by Q7 and D6/D7. The output from the speaker is rectified and used as a kind of varying "bias" voltage for Anti-vox function based on level of output from Q6.

So the signal I wanted someone to measure was the DC voltage at TP-2 produced when there was no audio from Q6 and when there was a strong audio output tone from Q6 being coupled to the speaker line. I did not state that very well.

One way to do this is to use the Marker signal.

Here is how I measured this DC level at TP-2 in a TS-830:
1. Antenna on dummy load
2. RFG at "5" (need to get a no audio voltage level)
3. AFG at "2"
4. Mode LSB or USB
5. Vox Gain off
6. Anti-Vox at Full CW
7. VFO 200, Drive control 1200
8. Marker OFF
9. Measure DC voltage at TP-2 with DMM. Need to wait until voltage decays completely off. Should see +0.001 to -0.001 dcv bouncing back and forth. So essentially zero DC offset voltage at TP-2 with no signal conditions.
10. Now turn on Marker and tune VFO for approx 800hz note and peak Drive control. Watch the DMM and tune the VFO for maximum DC voltage. Should see something like + 0.0305 vdc. Just tune VFO and Drive control for maximum voltage.

When you turn off the Marker you will have to wait awhile for voltage to decay to lowest no audio signal level.

If Craigs Anti-VOX is not producing this 0.0305 vdc bias voltage then speaker sounds will produce sufficient signals to key the rig thru the mic. Cleaning and exercising the Anti-vox pot as suggested my Mike W5RKL would be first thing to try. If there is no power amp audio coming from the wiper of this pot then the Anti-vox circuit cannot produce the necessary bias or offset voltage. If cleaning pot doesnt produce 0.030 vdc at TP-2 then have to trouble shoot the Anti-vox circuit.

Another way to get a test tone out of Q6 Audio Amp would be to inject modulated RF into SO-239 from RF signal generator that has internal or external modulation capability, but suspect Marker test is as good as any.

Dave:

See my Step 5. You need to turn off the Vox Gain pot. Relay should not be tripping.

You dont want any audio coming down the mic line from tone being emitted by the speaker.

The objective of this test is to see what is the maximum dc threshold level that the Anti-Vox circuit can produce at TP-2 in presence of strong audio output signal from Q6.

Hi folks and thank you for letting me join the group....I will strive not to let my questions sound to neophyte...
Has any of the group or anyone the group has heard about ever use the Headphones/boom mic that is offered by Bob at W2ENY's design center?????He has web site and the combo he sells should fit on my old 520s nicely but I have apprehension about pulling the trigger on the purchase......
I did write Bob and asked him if the ceramic mic would exhibit audio that is too High(treble)? That is usually the case with ceramic/crystal mics. I know the old Kenwood's have world renowned audio quality and I certainly want to keep that quality.
Any help on this issue would be highly appreciated......
Thanks again and Best of 73.s

Hi Mike,

The key in any microphone and headphone use is to match the transceiver's microphone and headphone impedance ratings with the impedance of the microphone and headphones.

The TS-520 has a "high impedance" microphone rating of 50K ohms and a 4 to 16 ohms headphone impedance. When you spoke with Bob, W2ENY, did you tell him about those impedance values? If not then I recommend you contact Bob again and discuss those impedance values with him. If there's a problem with impedance, especially in the microphone, then ask if he sells an adapter, low to high impedance, that will allow the headphone/boom microphone system to work with the 520.

The tool I got from Ken K4EAA has worked very well and my ferries were a little stiff from non-use even after using penetrant.

Would love to get/see one if original tools supplied. Have never seen one mentioned with any hybrid for sale, at least not here in G-land.

I have had no problem with Kens tool. Have several of them.

I still feel GC(Waldom) makes the best alignment tools. I have very old complete TV/Radio set. They also make several other smaller sets including an 8 piece CB set for starters or you can buy individual pieces and make up a set. They sell tools made from Delrin and the new anti-static ones.

I have never tried the Ceramic tip tools.

42983. Phase lock loop indicator on the TS-530 and TS-830

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-23 11:07:23 UTC
From: wa4axt
Topic: 42983 Message: 42983

If you were to look at older transmitters that use a phase lock loop oscillator , you would find that such units had a light that tells the operator that the loop is locked on to the desired frequency and its ok to transmit .Unfortunately Kenwood in the printing of the owners manual for the TS_530S and probably the TS-830 did not inform the owners of these radios that they to have a lock/unlock indicator . The indicator is the units digital display . If the display goes blank on a TS-530S then that means that your pll has lost its lock . This loss of lock can occur if for example you are using a long wire antenna and some rf gets into the pll circuit or if your pll circuit is out of tune .Sometimes it happens briefly on 10m if you spin the vfo dial a little fast as the pll tries to catch up . I thought I would mention this point because when it first happened I thought I was experiencing a display failure.In conclusion I just want to point out that just because your vfo display blinks doesn't necessary mean your radio broken because their is a circuit in the radio doing the blinking to inform you of a condition .

Note: If you should see your display flicker when transmitting , then you need to stop transmitting immediately because your vfo is scanning as it tries to re lock and as a result your spewing garbage all over the radio spectrum .

Having a good set of alignment tools is a must for the hybrid radio owners

I see Amazon has a nice collection,but i have never bought anything from
them yet.
It's the smaller tips i find that's hard to keep their shape or strength
and i think the ceramic would be a good choice,but have not seen any for
rf coils
The last set i got is fine if there is no resistance,,example i have a
few coils with the rubber bands in them,and it takes a bit more force.
I guess if you took a small piece of hardwood you could whittle one out.

I mean no disrespect but I disagree with your statements pertaining to the 530 VFO and PLL units.

First, the PLL unit does not "try to catch up". I have no idea what you are trying to say with that statement.

Second, you said "your vfo is scanning as it tries to re lock". Not true, the VFO's do NOT scan and they, themselves, do not "relock".

You said that when the display blinks that there's a circuit that's informing the operator of a condition. What are you trying to say?

I recommend you take some time and thorough study the operation of the PLL Units in the 530, 820, and 830.

Hi Terry
I have a full set of ceramic alignment tools
Only one thing to say about them.
Outstanding.
Regards,
Michel vk3kvw

I have had no problem with Kens tool. Have several of them.

I still feel GC(Waldom) makes the best alignment tools. I have very old complete TV/Radio set. They also make several other smaller sets including an 8 piece CB set for starters or you can buy individual pieces and make up a set. They sell tools made from Delrin and the new anti-static ones.

I have never tried the Ceramic tip tools.

Hi Michel:

I have been thinking about buying a set for some time now. I was just worried about them being easy to fracture. I will do some Google search and see what is available state side. Sometimes Amazon.Com has good prices. Do you know if the brand you have is available here?

Thanks

Topic: 42983 Message: 42989

Bob,

That statement,

"if the PLL unlocks for any reason, it will be detected from the phase comparator output."

as it's written in the service manual, is somewhat misleading.

A PLL (Phase Lock Loop) consist of numerous circuits which include oscillators, mixers, BPF (Band Pass Filters) and dividers that are all part of the "PLL Unit" as a whole. Not all oscillators are on the PLL Unit, some are external such as the VFO for example. The PLL does not tell itself to LOCK or UNLOCK nor does the PLL Unit itself turn the display ON or OFF. Changes from LOCK to UNLOCK and vice verse as well as turning the display ON or OFF, are determined by the PD UNIT (Q19) within the PLL Unit.

Studying the PLL Unit's block diagram in the service manual on page 4 shows how the PLL Unit, the CAR Unit, and the VFO Units all work together.

The PLL Unit in the 820, 530, and 830, do not "catch up" nor do any of the hybrid VFO's "scan".

Thanks for the input Mike.......W5RKL
I did E-mail Bob W2ENY and he stated that all his mics are ELECTRET . His web sight states that he does have a model suited for several Kenwoods and cited the 520s by number.....
I have the credit card ready..... I'm STILL tentative..... I haven't got the discretionary income that a lot of amateurs seem to have(Good for them ,however).(I sight the costs of a new ,full blown, Icom rig. Geez!
I'm still trying to keep the fun in this hobby....Oh well.....

Thanks,once more and best of 73's to all

42991. TS520 S-Meter

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-23 20:08:14 UTC
From: n3kvl
Topic: 42991 Message: 42991

Hi All,

A peculiar symptom has developed in my TS520S.

When the unit is first powered on, the S-Meter rises to about S3 then slowly drifts back over time as it is on.

What may be causing this effect?

Thanks
Archie

42992. Re: [TS-520_820_530_830] Re: Phase lock loop indicator on the TS-530 and TS-830

I made a "typo" by indicating "Q19" as the PLL Unit's "PD" when the PD
is actually Q17. I don't know why I hit the "9" key instead of "7" key.
The PD, as I said, is the stage that changes the state of the PLL from
LOCK to UNLOCK and vice verse plus the PD issues and removes the digital
display blanking signal.

42993. Re: TS520 S-Meter

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-23 21:47:23 UTC
From: Terry Wagoner
Topic: 42991 Message: 42993

It is normal for all Hybrids to have the S-meter go up scale on power on. It will be much more pronounced if you have the antenna connected when you power the rig on. If you leave the SO-239 grounded thru your antenna switch or on the dummy load the affect can be greatly reduced.

Two things are occurring almost simultaneously. First you have to understand that your S-meter is a reverse reading volt meter that is monitoring the voltage on your AGC bus line. When you have approx 3.2vdc on the AGC bus the S-meter should read 0 and when you receive a signal the AGC detector/Amp pulls down the AGC bus voltage and the S-meter then reads up scale. The stronger the signal the lower the 3.2vdc bus voltage will go down and the S-meter will go up scale.

So when you 1st power on the rig with an antenna connected the AGC bus line is coming up from zero to normal 3.2vdc being powered by RF-1 from your AVR board. This voltage is charging the AGC timing caps and bringing the bus up to 3.2vdc. At the moment of power on the S-meter sees Zero volts on the bus and goes up scale. Also the moment you power on you have signal applied to the front end of the radio which the AGC amp and Detector sees and tries to pull the AGC bus voltage down which also drives the meter up scale. As I said sometimes hard against the peg.

Most people like to avoid slamming the meter indicating needle against the peg on power on so they leave the rig SO-239 on ground. It serves to prevent nearby lightning induced ESD into the front end and stops the S-meter from pegging. ESD much more serious threat than pegging the S-meter. Can result in losing antenna step up transformer and RF amp on RF board.

Now if your decay back down to zero is taking an inordinate amount of time you may have a problem with one of the AGC time constant electrolytic capacitors. How long is it taking for the needle to return to Zero?

42994. TS-830S low output in TUNE

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-24 01:33:05 UTC
From: Craig Roberts
Topic: 42991 Message: 42994

So -- what causes low output in TUNE?

My TS-530S puts out about 20 watts in TUNE /SEND position at resonance

MY beleaguered TS-830S yields about 1 or 2 watts under the same conditions with meter readings too low to be useful for plate dipping. Output in CW / SSB mode is normal, though the 830 will oddly load up to 300 mA (no -- I don't run it at that, I stay about 230 mA).

It's not the driver tube (I swapped it with the known good one from the 530).

Whatcha think? (BTW, the leading "0" display problem has been replaced by an intermittent "1" on the 14 and 18 MHz bands).

Thanks again!

Craig
W3CRR

42995. RE: [Bulk] [TS-520_820_530_830] TS-830S low output in TUNE

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

From: Brad Allen
Topic: 42991 Message: 42995

I messed with one of these once, changed the driver tube just because and found out later the wire to the filament was defective from the socket to the board. Replacing the wire fixed it right up. I hope you are testing into a dummy load as I am not sure how you know anything is at resonance. Brad KB2CHY

Subject: [Bulk] [TS-520_820_530_830] TS-830S low output in TUNE

So -- what causes low output in TUNE?

My TS-530S puts out about 20 watts in TUNE /SEND position at resonance

MY beleaguered TS-830S yields about 1 or 2 watts under the same conditions with meter readings too low to be useful for plate dipping. Output in CW / SSB mode is normal, though the 830 will oddly load up to 300 mA (no -- I don't run it at that, I stay about 230 mA).

It's not the driver tube (I swapped it with the known good one from the 530).

Whatcha think? (BTW, the leading "0" display problem has been replaced by an intermittent "1" on the 14 and 18 MHz bands).

Thanks again!

Craig

It sounds like you have bad Screen Grid divider resistors R15 and R16 56K ohm on Rect Unit board. If you are comfortable taking voltage readings you can measure screen grid voltage at Pin 3 at the 6146 tube socket. Suggest you replace both resistors with metal film units even if you find only one bad.

Jim, here. Sounds to me like the normal operation of the AVC circuit.
If the front panel switch is set at "Slow," it will take the AVC time to
recover to noise background. If the AVC switch is turned off, the meter
will recover quickly.

Best,

Jim Shelby

Hi Terry.
The brand I have here are tools from Taiyo in Japan.
They are sold in Sydney in Australia.
Complete packages or individual tools are available.
I don't know if they are available in the USA but one would think so.
If not then I am sure I could do something for you from here.
Let me know.
I hope you are feeling well again.
Regards,
Michel vk3kvw

Hi Michel:

I have been thinking about buying a set for some time now. I was just worried about them being easy to fracture. I will do some Google search and see what is available state side. Sometimes Amazon.Com has good prices. Do you know if the brand you have is available here?

Thanks

The suggestion to turn the AGC to OFF position has been mentioned here more than once in recent past. Why should a person have to remember to turn the AGC to off as part of normal power down operation to prevent pegging of the S-meter and decay back to zero on the next power on cycle?

Good practice would be to turn the Antenna switch to the ground position to accomplish two objectives: 1. Protect front end of radio from nearby lightning 2. Prevent pegging the S-meter on the next power on cycle. Grounding of SO-239 or removal of PL-259 prevents S-meter pegging/decay action on radio power on.

It seems to me much easier to faithfully develop this habit as opposed to turning AGC to Off. If you have no grounding antenna switch in your installation then you are inviting loss of antenna step up transformer and/or your RF amp. Only other way to protect against that is to unscrew the PL-259 which isnt very convenient. Antenna step-up transformers are unavailable and must be rewound. Can be done but preventive action makes more sense than corrective action to me.

43001. TS-430S AND ITS USE OF ITS DISPLAY AS A LOCK INDICATOR

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-24 11:00:43 UTC

Topic: 42983 Message: 43001

http://s237.photobucket.com/user/rtaylor0361/media/Untitled_zps17e7540d.png.html

The link above describing a loss of lock condition in this 1984 Kenwood radio and its use of the display as a unlock indicator shows that pll drift related to a un-lock , open loop condition was a problem even as late as 1984 in some pll equipped radios.

43002. Re: Phase lock loop indicator on the TS-530 and TS-830

http://s237.photobucket.com/user/rtaylor0361/media/287736_zps01116034.jpg.html

Shown in the link above is a 1978 transceiver with a lock indicator .It was not unusual to see such early pll radios with such indicators .At some time in the future , the fcc required manufactures to install hardware that monitored the loop for a open loop condition and shut down the transmitter if the loop is broken and the vco tries to scan for re-lock . When the lock light was on the radio shown above ,the user could be assured that the VCO in the pll circuit was operating in its closed loop mode and the vco was locked to the desired frequency . If the light was off , then the pll was in open loop mode with the vco frequency drifting or scanning up or down to acquire a re -lock of the pll loop . I recently had to replace my pll board on my TS-530S after receiving reports from other hams that I was creating noise up and down the band . In hind sight I recognized that such action occurred when the digital display would flicker . This flicker unlike a lock/unlock light was just barley noticeable and that one had to be looking for it to happen to know it happened . That's why I am bring this condition to the attention of the group . I guess that by the early 1980es Kenwood thought it had the pll lock/ unlock condition licked and saw no need for a specific indicator light , but after 30 years , the pll boards alignment on these old radios radios have probably deteriorated and that's why the vfo unlock condition may be occurring I would guess.

Thanks, Terry.

When replacing components on the rectifier board, can the board be simply flipped after removing the hold-down screws or is desoldering some or all of the many wires to the board necessary? The wires all appear, if memory serves, to be attached from a harness on one side of the board. (I ask because I am not in the vicinity of the radio to check for myself).

If it is the latter, I am tempted to cut the resistors out from the top and splice the new ones in on the lead stubs (though, as a quasi-purist, I'd rather do it the "right" way providing I can avoid damaging fragile circuit board traces.

I think I'm going to sell my Yaesu FT-757GX Mark I setup - looks like I can get more power out of my TS-820 once I get it fixed and could put the money into a good antenna setup. I'm going to get a local guy to see if he can help me get the 820 back to transmitting since since it's not showing anything out right now, but it is receiving well.

I currently have an 88' end fed antenna going out to a limb about 25' up in my front yard that picks up decently well and transmitted the other day to West Virginia, but I'm curious about what kind of antenna setup you guys have.

I want to optimize what I can, even though I don't have a huge yard and am limited because of a long power line in my back yard. After using an 80 meter dipole about 55 feet in the air Saturday at Field Day with a strong Kenwood TS-2000, I got spoiled and want a nice setup - I'm tired of calling at home (using the Yaesu since the 820 isn't transmitting) and not getting many responses.

The trees that I have I'm afraid might snap a dipole if I put it up in the middle of them when we have the thunderstorms the South is so well known for, especially during the Summer. So far the end fed has survived, but we haven't had any massive storms since I put it up.

Going purely on eham.net's reviews the Zero Five antennas have great words said about them. I might consider something like this vertical:

http://www.zerofive-antennas.com/43-foot-10-160-meter-multiband-foldover-freestanding-vertical-antenna-5kw-ununn

It would be in my front yard about 10 feet from my house and 25 feet away from trees because that's about the only place I could put it.

I don't want to blow a lot of money on antennas, but I do want something really nice for $300 - $500 if possible. I know I won't get a blow it out of the water antenna for that money, but I'm curious to see what you guys could give me insight on.

Thanks as always!

Barry

Bob,

You said:

"If the light was off , then the pll was in open loop mode with the vco frequency drifting or scanning up or down to acquire a re -lock of the pll loop."

With all due respect, the portion of that statement where you state, "the vco frequency drifting or scanning up and down to acquire a re-lock of the pll loop" is not true. VCO's themselves do NOT scan up and down on their own for a re-lock. You keep incorrectly stating that a VCO scans to obtain a re-lock and that's simply not true! A VCO is controlled by the PD and ONLY the PD determines whether a LOCK is achieved or not, NOT a VCO on it's own!

I have no idea what you mean by "open loop mode". Explain in detail if you would please, what you mean by "open loop mode".

You said you replace the PLL board in your 530 because because a few stations told you that you were "creating noise up and down the band" and that the display was flickering. I would not have replaced a board based solely on those symptoms and reports! I would have a few questions about the reports from distant stations. Some question which are:

1. Is the noise caused by "splatter"? (Mic gain set too high)
2. Is the microphone I'm using causing distortion which appears to the distant station as noise?
3. Does the distant station have it's noise limiter turned ON due to local noise at the distant stations location? (will create similar noise indications)
4. How does the distant station know it was you, i.e., what evidence proves it was you?
5. Did you ask the distant station if they could have recorded your transmissions and play it back to you so you can hear what they are hearing?
6. Did ALL the stations in the QSO tell you the same thing or just one?

Also, what troubleshooting steps did you take that produced results that told you the PLL board could not be repaired and had to be replaced? A few simple steps such as

1. Did you check the board's mounting screws to ensure they are tight?
2. Did you clean the board's plugs to ensure they were not causing any PLL problems?
3. Did you clean the VFO's variable capacitor shaft to frame connection

4/ Did you check the individual oscillator frequencies applied to the
PLL board to ensure they are stable and the signal levels were what they
should be?

Those are a few simple steps that should have been performed first
before replacing the PLL board.

I never said the display was NOT an indicator of a PLL UNLOCK state. I
did, however, ask you what you were trying to say about a blinking
display and a circuit that's telling the operator something and so far
you have not answered that question.

Craig:

Based on my experience of having replaced multiple components on a TS-820S rectifier board and having replaced an entire TS-520 rectifer board, you should be able to replace those resistors without entirely removing the board from the radio.

You are right to be concerned about the fragility of the circuit board traces. The age of the board combined with the tmperatures in that area result in the traces being very fragile indeed. But access is not that bad and it's not that hard to replace those traces with short lengths of wire if damaged.

Good Luck!

Robert

Various factors have led me to be limited to the most basic of antennas -- the simple dipole. While I have been modestly successful in the past with these band-specific hunks of wire at a mere 25 feet AGL (above ground level), the Kenwood hybrids, TS-530S and TS-830S, that I have acquired recently have proved to be transformative. The receivers in these 30-year old machines easily equal and, at times, outstrip the newer ones I have tried. But, the real improvement has been in transmission. Perhaps because of the clarity and fidelity of hybrids' transmitted audio, I am able -- for the first time with these modest antennae -- actually work everyone I hear. I am also delighted to not only be detected at the other end, but, more often than not, complimented on the high quality of tghe audio originating from Kenwood's equally excellent MC-50 dynamic microphone.

I can only imagine what ham life would now be with a no-holds-barred gain antenna at optimal height.

73,

Hi Barry,

If one or both ends of your wire antennas are affixed to trees- use a pulley and weight to accommodate the movement of the trees.

At HF, manmade noise is primarily vertically polarized- so I would think a vertical antenna would only exaccerbate your noise problems. However, a horizontal dipole could be as bad if you do not take steps to eliminate common mode from the coax- typically by using an appropriate BALUN.

GL,

Dale W4OP

Subject: [TS-520_820_530_830] Curious about your antenna setup with Kenwoods

I think I'm going to sell my Yaesu FT-757GX Mark I setup - looks like I can get more power out of my TS-820 once I get it fixed and could put the money into a good antenna setup. I'm going to get a local guy to see if he can help me get the 820 back to transmitting since since it's not showing anything out right now, but it is receiving well.

I currently have an 88' end fed antenna going out to a limb about 25' up in my front yard that picks up decently well and transmitted the other day to West Virginia, but I'm curious about what kind of antenna setup you guys have.

I want to optimize what I can, even though I don't have a huge yard and am limited because of a long power line in my back yard. After using an 80 meter dipole about 55 feet in the air Saturday at Field Day with a strong Kenwood TS-2000, I got spoiled and want a nice setup - I'm tired of calling at home (using the Yaesu since the 820 isn't transmitting) and not getting many responses.

The trees that I have I'm afraid might snap a dipole if I put it up in the middle of them when we have the thunderstorms the South is so well known for, especially during the Summer. So far the end fed has survived, but we haven't had any massive storms since I put it up.

Going purely on eham.net's reviews the Zero Five antennas have great words said about them. I might consider something like this vertical:

http://www.zerofive-antennas.com/43-foot-10-160-meter-multiband-foldover-freestanding-vertical-antenna-5kw-unun

It would be in my front yard about 10 feet from my house and 25 feet away from trees because that's about the only place I could put it.

I don't want to blow a lot of money on antennas, but I do want something really nice for $300 - $500 if possible. I know I won't get a blow it out of the water antenna for that money, but I'm curious to see what you guys could give me insight on.

Thanks as always!

Barry

Barry that 757 Is not a bad radio and I am not normally a YEASU fan, and the 757 has it's share of receive sensitivity issues.. I am Kenwood 100%. I have 4 TS-940 units, not to mention the TS-930 in mint condition and I have a TS-2000. I prefer the 940 over the 2000, but operate the 2000 just as much. My antenna, well I could string wire all over the place and I don't. You can fold antennas, slope them to get the length you can work with etc. Even on a small lot, you can do wonders. I have a good suggestion. I have a COMET CT-250B. I will tell you right now it's good for 200 watts only, but then again, I don't run more than 100 or so. It is a vertical which really needs no radials, but a ground is necessary. It works well, looks good if seen and is not priced all that high although is not cheap. Solid construction and I got free support even after 6 years of ownership. 3 screws and a couple clamps get it about 30 ft off the ground and you are good to go. Ground rods for RF are best placed at a angle as RF only penetrates a short distance below the surface.

Your theory of getting contacts is not really correct. Putting the money into the antenna and quality coax is what you SHOULD do. So you have a Kenwood that has a hot receiver, they are noted for that anyway, so split, use the 757 transmitter and the Kenwood receiver, with a switch over network for a while. Split operation like that is done a lot. It really is the antenna and the coax that makes the station and a decent radio helps, but is not the key to contacts. Neither is raising your power. You have to DOUBLE your power to move 1 s-unit on a meter. Even if you could get 200 watts out of your Kenwood, you would be disappointed with the results. It takes careful listening and operator patience to snag the world with a modest in your budget type station, but don't be embarrassed about it.

Another antenna is a dipole and gave me awesome results were a COBRA Senior. You could also try a COBRA junior as well. You have what you have for equipment; maximize it with a decent antenna that will give you reasonable results. Brad KB2CHY.

Barry,
You would be so much happier if you built an antenna yourself. Spending that kind of money on a wire does not make sense once you have discovered that you have the power to make antennas for very little.

Perhaps if you describe your lot size, house placement, fences etc. others may chime in with a practical design which works for your situation. A simple dipole is hard to beat for the money.
With a tuner, my HomeDepot 14 gauge electrical wire 80 meter dipole gets out on 80, 40, 20, 17 and 15 meters. I worked south Brazil last night on my TS530. You can too.

Jerry:

First of all the panel meter is always in ALC or S-meter function in Receive mode where ever you have the meter selector switch set at. When rig is in Send then the meter switch can be used to select the transmit monitoring positions of ALC, Ip, HV, and RF.

The 520S and SE are virtually the same radios with some very minor exceptions. The AGC and S-meter circuits are identical and should behave the same as the 520S.

I have very little hands on experience with the 520SE, but quite a bit with the other hybrid models. So I cannot tell you with 100% certainty that your S-meter should not peg and then decay back to zero in initial power on with the antenna removed, grounded or on a dummy load.

I can tell you that I have never seen a hybrid that does not work in that manner. In my experience with the antenna feed line grounded or removed from the rig about highest meter deflection I have see is approx S-3.

So do I understand that if you ground your SO-239 or unscrew the coax feed line from it and then power on the radio that your S-meter will peg FSD and then drift back down to zero? If this is true I have no explanation for that behavior.

Perhaps other TS-520SE owners can comment here.

To Barry (no ham call given) and all.
I would not blow $400 on a piece of aluminum pipe. not a cost effective solution.
I would go to the big home improvement store and buy a 150 ft roll of #14 THHN wire , some pully assemblies and get on line and order some end insulators and a roll of coax (someone always has ads in the ham magazines for coax) and some PL259 connectors, insulators and put up a dipole with weighted pully strain relief on the ends. If you want to invest another hundred + , get a balanced line tuner and do the twinlead feedline instead of coax feed for multibands with one long dipole.
You have to decide what band or bands you want to start on and calculate dipole lengths for this band.
Last BUT NOT LEAST. you cant work DX easily with a low antenna, GET IT HIGHER way up in the trees you have..
Good luck

Thanks, Robert.

Given the risk to circuit board traces, and lacking at present the magical Hakko 808 desoldering thingie favored by Terry and friends, I may just go the "topside splicing route", at least for the time being. If the new resistors actually do the trick (and the schematic indicates they may very well correct the glitch), I may then formalize the installation from the copper side. I dunno.

Frankly, I'm not sure I'm any happier with the possibility of having to install wire jumpers on the bottom of the board than I am with splicing in components from the top. I have used the splicing technique for years on antique radio restorations and have thus avoided damaging fragile connection points and adjacent components. It's not as pretty as complete component removals and replacements, but it's safer, easier -- and it works.

Hey -- if this decision is the toughest I have to make right now, life's going pretty darned well, eh?

Oh, last night I discovered that I have on hand every imaginable metal film resistor manufactured -- except a pair of 56K 1/2 watters :-) .

43017. TS-820S RF-clipper vs normal mode TP2 IF-unit

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-24 16:00:35 UTC
From: hfdxer@ymail.com
Topic: 43017 Message: 43017

Recently I repaired a TS-820S which will be donated to a young HAM.

Yesterday I made a few QSO's with it and received good audio reports.
From the reports I received, there was not much difference between PROC ON and PROC OFF, also noticed by the average power reading on the Watt meter here. Actually, with PROC OFF I could get more avg power.

I am now in the process of checking/adjusting the rig cf. service manual specs in total.

When arriving at the RF-clipper part, I could not get the same audio levels between PROC ON/OFF into the 1st TX-mixer, as measured at TP2 of the IF-unit.
The carrierfrequency is 451.90 kHz.

Situation:

MIC GAIN is at 12 o'clock:

With the RF-clipper on, I measure a beautiful sine wave, when whistling, with 560 mVpp, measured at TP2 with VR7 at max.

With the RF-clipper off, the peak-peak voltage is significantly higher and with strong whistling I can reach 2.8Vpp (~4 x 560 mV (!).
At this level the audio is distorted as I see flattened tops.

When the MIC GAIN (front) is turned fully CW:

With the RF-clipper on, I reach 2.8Vpp, with VR7 max. No distortion.

With the RF-clipper off, I reach the same 2.8 Vpp easily and create square waves ;-)

It seems to me that the level of the first MIC amp (Q19) is (much) higher than the output of the clipper amp (Q23).

If I am reading the circuit diagram correctly, the outputs of both Q19 and Q23 are fed into Q20.

I also varied the LO-frequency to determine if there might be an optimum in the three 455 kHz filter responses, but no gain.

To equalize the two levels, I'm thinking of shortening R121 (1k) in order to increase the gain of Q30, and/or lowering R122 (47k)

Before doing that, perhaps somebody could help me out on this?

73, Remco PA3FYM

What size dipole do you have, Craig? The ones we were using Saturday were about 50' or so in the air and looked to be 80m sized dipole setups. Every contact we tried to make, even though there were several pileups, we pretty much made. That was on the TS-2000, and I bet if I'd been able to transmit with my 820 it would have worked well, too.

I know there's no way for me to get a 50' high dipole up, but I might could get 30' or 40' high. There again, I'm afraid my trees may rip it apart during a storm with limbs flinging everywhere.

There is nothing at all wrong with a vertical that works. You don't spend $400.00 on the pipe, the bulk of the cost is the fact you won't need a tuner at all because the comet has a network that brings the SWR low in the Ham Bands. Most dipoles need a tuner which just says you are tuning random and therefore is eating up power in heat and components. Just because the dipole can be TUNED does not make it efficient. The COMET is an efficient compromise antenna. It does in fact work, and that is what counts. Brad KB2CHY

From: John Davidson
Topic: 42991 Message: 43022

The tune position has contacts with resistors connected to lower the screen voltage etc. to run reduced power while initially tuning, to prevent tube damage by overcurrents.
Low output in normal operating (CW) position requires troubleshooting.

Subject: [TS-520_820_530_830] TS-830S low output in TUNE

So -- what causes low output in TUNE?

My TS-530S puts out about 20 watts in TUNE /SEND position at resonance

MY beleaguered TS-830S yields about 1 or 2 watts under the same conditions with meter readings too low to be useful for plate dipping. Output in CW / SSB mode is normal, though the 830 will oddly load up to 300 mA (no -- I don't run it at that, I stay about 230 mA).

It's not the driver tube (I swapped it with the known good one from the 530).

Thanks again!

Craig

Hi All
Early TS830's
I am finding out that the early 830's had problems with soldering,and was corrected With the later models
Before you reinstall a board,check all the connectors as i had #8 & #9 plus the vco connections[rf board] all lose and had to resolder them as i kept losing my drive.
Check to make sure the board is well grounded.

I am looking to but a DS-2 for my Ts830

The pll in the TS-530s is a form of feedback controlled device where its output is a function of its input , which is usually a reference oscillator , and its output . as shown in the drawing in the link below .

http://s237.photobucket.com/user/rtaylor0361/media/imagesCAIUH2LH_zps668f2415.jpg.html

The vco will move to what ever frequency it needs to move to in order to drive the output of the phase detector to zero (locked condition) . For example if your reference clock is 1 and the divider is set to 1 then the output of the vco will be 1 (1-1=0) . If the divider is set to two the then the vco output will be two because that's what the vco has to output in order to get a 2/2 (output of the divider) -1 (reference oscillator) = 0 to the phase comparator . How much the vco bounces above and below the desired frequency before it locks on to the desired frequency is dependent on the loop filter that feeds the vco.
I am not to great at explaining things things so I hope you can grasp what I am saying .

In conclusion the thing to realize is that in a feedback system the vco output is a function of both its output and input and the radios programmable divider forces the vco to move to the frequency you want the pll to output. .

Note: The problem with my signal was confirmed by me using a remote hams.com receiver .

I have a kenwood 520 and 830. For the low bands I use a doublet antenna. 20- 6 meters, a K4KIO Hex Beam. I would invest the $500 in a hex beam. They are light, low swr, and a great performer. Check out http://www.na4rr.com/. He sells a low cost hex beam.

Topic: 42991 Message: 43027

Thanks, John,

I enjoyed reading your QRZ.com narrative!

The theory (thanks, Terry) is that at least one of the two 56K resistors of which you speak has gone south. Output in the TUNE position is now only a watt or two as opposed to the normal +/- 20 watt output I get on my companion TS-530S. This makes tuning up in the TUNE position problematic since meter deflection in the iP position is too little to be at all useful in preliminary dipping of the plate.

CW output is normal (100 + watts on all bands except on the possibly misaligned 160 meters), so, operationally, the TUNE glitch is more of an inconvenience than a real problem. I overcome it by tuning up with manually reduced power (like every other "conventional" radio I've owned), but I hate to have a radio that's not fully operational in all respects, even if there's a "workaround."

73 and thanks again, John,

Craig

Your counsel is good. I never return any board without inspecting all molex connector pin soldering under good light and magnification. I plug a molex plug into the socket on the board to ensure each pin is seated and then wiggle the plug as I observe. Very common to find pins that are essentially floating as if the factory solder never wetted to the pin. I remove all the old solder and polish the pin to remove any oxidation and use a small amount of liquid flux to resolder. Trying to simply reheat is usually futile. Failure to make this inspection is silly as you have already invested the time in board removal. After you pull more than one connector off a board or return it and have to remove it again (rework) you will be a believer in inspection.

Only other problem that is hard to detect is if the trace has cracked at the transition to the Pin pad. This does happen and can be hard to spot. Removing all the old solder helps you spot a moving pad.

Remco:

The service manual processor alignment steps are flawed much like most of the manual.

Go to Ken K4EAA website and look under FAQs and read his alignment procedure.

Requires an audio generator and an O-scope. Set audio generator for 1000 hz and a level of approx 3 to 5 mv. Connect scope to TP-2 and adjust Processor 455Khz carrier oscillator trimmer TC-4 for maximum P-P level at TP-2. You will then change generator to 300 hz at same output level and adjust TC-4 for half the P-P level you had at 1000 hz. You are adjusting the -6dB point on the slope of the 455khz filters. You will have to go back and forth couple of times to get it right.

Just follow the rest of Kens procedure. I have used it and it works well.

If you have any questions about the procedure come back and ask. It is pretty straight forward.

Hi Bob:

I have had several rigs here where owner applied JB weld or some kind of epoxy around the Molex connectors. I think they did this as they experienced pulling connectors off the boards and it is there attempt at a fix for that. Anyone who owns these rigs or works on them enough will pull a connector off a board. Not fun but it happens. I can see where someone might think based on that experience they should glue the connector body to the board as a cure.

I dont think there is any good reason to do this. First of all I dont think Kenwood ever envisioned frequent need for unplug/plug cycles on these connectors.

I never rock the plugs side to side as I apply upward pressure as I fear cracking the trace to pad junction. I always try to apply upward force and gentle end to end rocking. End to end is far less likely to rock a pin in its pad. If you make sure all pins are soldered well and you Deoxit the male/female interface and get a good wipe on them then should never be any reason to have to pull them to address intermittent problems. Certainly not with any regularity.

I think I see more cobbled up IF boards than any other due to the frequent removal and install of filters.

So I never glue any molex connectors to the boards. I am not sure that I could spec a glue that would bond well to this connector material as I do not know precisely what it is made of. Perhaps nylon?

I grew up in a maintenance world where we did not use glue to restore bearing fits or for any other repairs. Glue was considered for the backyard mechanic. Welding repair was done and fabrication of new parts, but never glue anything together. I know modern glues have come a long way, but I just cant bring myself to glue the Molex connector to the boards. Old fashioned notions.

How high do you have yours? I MIGHT could get one 35 feet in the air, and I might be able to get one 102' long or so.

What constitutes an "early" TS-830S, serial number-wise?

The epoxy discussion reminds me of an incident from my Heath Company days. I was in the marketing department and among my duties was visiting Heathkit retail stores to assist with customer service practice compliance. The corporate promotional slogan at the time was "We won't let you fail." It was a kindly but unfortunate sentiment.

One evening at the Cleveland east side store, a short, stocky, hirsute gentleman of apparent eastern European extraction (his surname comprised a nearly unbroken series of consonants) struggled in singlehandedly with a huge GR-900 Heathkit console TV in tow, complete with weighty cabinet. He slammed the behemoth in front of the service counter, pointed to the "We won't let you fail" sign overhead and growled, "I fail -- you fix!" It took three of us to drag the TV into the back room, wherein our tech extracted the chassis, and, after removing the CRT, flipped it over.

At first we were baffled by what we saw, but soon determined that the television had been assembled with Liquid Solder -- the components literally glued together. After peering out into the showroom and regarding the customer's dark and glowering countenance, it was determined that our best course of action was to order a new chassis kit from Benton Harbor and assemble it for our dissatisfied client. This we did over the course of the next two weeks.

If you ever wonder why Heathkit went out of business, consider this story. Some say Zenith killed the company. Now, what do YOU think?

Hello Barry,
I have been following your posts about your antenna dilemma. Now, please do not be offended. YOU need to do some studying before you wade into this arena. The best Hybrid in the world will do you no good until you have informed yourself about how antennas work and the fact that they are the most important part of your shack. I have been constructing antennas since the mid 70's. I hold only a General ticket but I have read and studied everything about antennas. Now most of the selection is usually left to ones own desire and their amount of back pocket money. I have seen every kind of antenna advertisement you can think of and I use dipoles and an old trusty long wire. Either of these antennas will get around the world plus you have the pleasure of accomplishment. " I built this and it works!" feels good. Now you need to obtain a mid 70's ARRL antenna handbook and while you are waiting for it you can get on hamuniverse dot com and glean some info from their antenna design section. Forget the razzle dazzle types and dig into the simple dipoles and end feds first. My advise is to build to resonance for whatever band you choose to operate. I am not a fan of multi band antennas but built correctly they do work fine. I have recently built some coaxial dipoles and have had good success. Their BW is very good and allows you to utilize a fairly wide portion of your chosen band. But start out simple. Also, I am hearing a good deal of bad press on tuners. I would suggest you invest in a good one and roll out a few hundred feet of minimum 14 gage plastic coated wire to start. Get your antenna as high as you can. But you can read all about the how to in the antenna handbook. Quite a few tuners on Ebay but I prefer hamfest buying. You get to see what someone calls mint condition. If you have any problems you are in the right group. Let me know how you make out if you choose to study. I wish you success on your upcoming upgrade attempt. 73, Don K5HFG

If you use a resonant dipole antenna with your hybrid you do not need an antenna tuner. It is built into the hybrid.

Good multiband antennas are difficult to build.

For a nice treatment of the flawed bazooka designs (which achieve their minimal increase in BW through loss and fat conductors- NOT through reactance cancelling) see:
http://vk1od.net/antenna/DoubleBazooka/index.htm

Walt Maxwell and Frank Witt have also contributed elegant math analysis of why the bazooka does not achieve its BW by the means proposed by the designers.

My experiences: The best antenna I personally owned was a tri-band 2 element Quad that I used to operate with a '520 many years ago. For those unfamiliar, this Quad had two pair of 15 foot bamboo rods in the shape of two "X"s, each X at the end of an 8 foot boom. The wiring for each band 20-15-10 ran around the perimeter of each X.

That being said, I purchased a SteppIR 20-6m Vertical a few years back, put in 16 radials, etc. It is...ok, it does load up without a tuner on all of it's bands. Barefoot, as below.

Two year's ago, to get on 40m, I decided to purchase a BUXCOMM 40 Windom (offset fed dipole). Up about 20 feet - best I could do. It has out shown the vertical under every circumstance. First DX contact with my TS-830s on SSB 20m I broke through a mini-pileup and worked Slovenia. The came SANDY..no tree, not much Windom left...will try again new QTH

Part 2

I bought a commercial Windom for convenience. They can be easy home built. Many designs, information, on the Net and elsewhere. In my opinion, it is a very decent multi-band antenna if you can get it above 25 feet or so. They are NOT short=space antennas. See EHAM reviews if you are interested in my particular antenna. The BUXCOMM website has a decent write up on the Windom concept.

As far as I know the 1,000,000 series were the first. Probably 1981. QST review was May of 81 as I recall. You see lot of the 1,000,000 and 2,000,000 series being parted out.

I have a 2 million and a 4 million series both full filtered. My 4 million was built in 1985 and I have the original purchase invoice.

I would not buy a 1 million series.

I have had a couple of 6 million series on the bench and one that had documentation of a new purchase in 1990.

There have been several iterations of IF boards with changes to the AGC timing constant capacitors for one thing.

Well, then -- my TS-830S is serial #1030340.

Shucks! I shouldn't have asked. :-)

Well, at any rate, it's pretty much working. I should receive my 56K screen voltage divider resistors in a couple of days. I'll let you know how that works out.

We've been very lucky with a simple G5RV Jr antenna we picked up at HRO in Salem, NH three summers ago.
We were heading back to Maine from some quick business I had to deal with in Connecticut and stopped by the store.
The antenna was on special for $25.00 and we couldn't resist.
Once we hooked it up 45 plus feet above ground and running about 130 ft of coax into the house it gives us 1:8 swr and below on 40, 30, 20, 17, 15, 12, 10 and 6m.
No tuner required using all three rigs: TS-830S, TS-120, Yaesu 897D.
We've made hundreds of DX contacts using 100 watts and a $25 antenna!

> Requires an audio generator and an O-scope. Set audio generator for 1000 hz and a level of approx 3 to 5 mv. Connect scope to TP-2 and adjust Processor 455Khz carrier oscillator trimmer TC-4 for maximum P-P level at TP-2. You will then change generator to 300 hz at same output level and adjust TC-4 for half the P-P level you had at 1000 hz. You are adjusting the -6dB point on the slope of the 455khz filters. You will have to go back and forth couple of times to get it right.

Subject: Re: [TS-520_820_530_830] Curious about your antenna setup with Kenwoods

We've been very lucky with a simple G5RV Jr antenna we picked up at HRO
in Salem, NH three summers ago.
We were heading back to Maine from some quick business I had to deal
with in Connecticut and stopped by the store.
The antenna was on special for $25.00 and we couldn't resist.
Once we hooked it up 45 plus feet above ground and running about 130 ft
of coax into the house it gives us 1:8 swr and below on 40, 30, 20, 17,
15, 12, 10 and 6m.
No tuner required using all three rigs: TS-830S, TS-120, Yaesu 897D.
We've made hundreds of DX contacts using 100 watts and a $25 antenna!

Topic: 43046 Message: 43046

I just got my 10 meter antenna in the air and tuned. Tried out my TS-520 tonight. Receives very well. Did the tune up in prep to transmit. Checked power output and external meter shows 70 watts on CW but on USB it bounces up to 10 watts and drops back to 0. If I hold the mic key down it will cycle up and down but no higher than 10 watts.
Any ideas?

I also pulled the cover off the other day to see what filters were installed. It has both the SW and the SSB filters but I see no way to switch off and on. What should I be looking for?

Better than having no TS830 and you have no idea if it has all original 1 million series boards in it. Just enjoy it and get it in best state of tune that you can.

My point was if you are shopping for a TS-830 try to get as late a serial number as you can. Probably most Ebay units are 2 million series rigs. No one seems to state or ask about it.

I guess would be true with just about any first production runs of anything. Pretty common for second run to have some changes. Some can be signifcant and others just enhancements. I dont know of any serious design flaws with the original TS830s that had to be corrected.

Hi Barry,
I have always had good luck with dipoles cut to resonance for the center of the band I want to operate in. One way around your worry about the winds snapping the ends of a dipole is to configure it as an inverted V which case the ends will droop and you can allow for plenty of slack. With a dipole cut to resonance you don't need a balun or even a tuner, unless you want to operate way off of resonance say on 80 meters. Dipoles are cheap and quite a bit of fun to experiment with. With all of your trees you could also considered a square loop and/or delta loop wire antenna (see the ARRL handbook for some recommended configurations).

For multi-band operation I found that a G5RV works quite well, although a tuner may be needed on some bands.

Good luck and let us know what you decide!

OK--I assume you have an O-scope? If not, and you have a Freq Counter you could go to TP-3 and adjust TC-4 for 455khz as a starting point.

Also there is a Service Bulletin No. 9 11/17/1976 that you can find with a Google search. I have never tried to run it. You may want to take a look at it. Many of these bulletins are flawed but I have no experience with this one. A cursory look tells me it looks OK.

Maybe one of the other members has had success with this procedure?

> > Requires an audio generator and an O-scope. Set audio generator for 1000 hz and a level of approx 3 to 5 mv. Connect scope to TP-2 and adjust Processor 455Khz carrier oscillator trimmer TC-4 for maximum P-P level at TP-2. You will then change generator to 300 hz at same output level and adjust TC-4 for half the P-P level you had at 1000 hz. You are adjusting the -6dB point on the slope of the 455khz filters. You will have to go back and forth couple of times to get it right.

Terry
It has $300 of Inrad filters in it.
It also has about one hr transmit time and about 7 hours of rec time

I could give you a better deal on the Ebay special hi hi
I have been at least a year playing with the Ebay special and just
getting it to respond back to my treatment.Lots of bad solder joints as
per my posts.
When doing receiver adjustments,i made a mistake by over looking
transmit if coil adjustment's.
I had to really turn up the carrier 3/4 of the way to get good drive
and by adjusting T4 it is now fine as it was way out of adjustment.
I am running a 6146b and a 6146a as that's all i had on hand,and
getting 100 watts out.
It serve's as a good trainer.

When is your book coming out!

Scott:

Very good advice. Last time I had a tuner was in the late 70s when I ran tuned feeders to get multi-band operation. Back then balanced tuners like the Johnson matchbox were the norm. I got tired of the hassle and went back to resonant dipoles cut as you describe and have run that way for years with the occasional foray into trap dipoles, fan dipoles, coaxial dipoles etc. I always ended back with resonant dipoles. I just put up my first home built OCF dipole fed by 4:1 current balun at the "sweet" spot and in inverted Vee config with apex at 45 feet and ends at approx 20 feet. It works very well. If I had listened to all the negative press would never have tried it.

I no longer have room for any loops, but as you note if you do they are worth trying. Wire beams are fun also. Many moons ago built 8JKs and ZL specials. Of course had the 14AVQ trap vertical, but never had a decent radial system. Never had room for phased verticals.

I guess about only one I would not recommend is random length end fed due to high Z feed point and the hassles of rf in shack and messing with counterpoise.

I always encourage any one with enough room to experiment with all kinds of wire antennas. Never let anyone tell you it wont work. Try it for yourself. It is one area left in the hobby where you can build it yourself and get the learning and self-satisfaction with not much cash outlay.

Hams have been looking for a simple, multiband, wide bandwidth, coax fed, no tuner antenna for years. I am still looking!

Don:

Well cant blame me for trying!

Yes with low TIF signal or low VCO signal the TX Mixer output will suffer. The TIF signal from the IF board is not much more than approx 15mv and Mixer needs approx 180mv to work well and about 1 volt of VCO LO signal. If T4 is not peaked will be a problem. You just never know what the former owners have touched.

I always recommend that people do the complete Sect 6 alignment steps in the Owners Operating manual to get them close and then go on later to a complete Service Manual alignment that requires some test gear. You can usually get rig in pretty good state of tune by just doing Sect 6 for RX and TX.

Sect 6 will direct you to peak T4.

No book any time soon. I have thought a lot about a You Tube Hybrid users video series, but have never made one and growing up in nuclear power I understand how important the quality of the video production is. Poor video production can easily spoil the message. I guess today an amateur trainer can get pretty good results with not large investment in a camera, mic and lighting.

Best teaching model is Tell, Show, Practice, Feedback/Coaching. With this medium all we can do is Tell. With Video can Tell, go to white board and Show, and then go to rig and test bench and demonstrate how to do. If well done only 2nd best to hands on with a live instructor.

A "B" and an "A"! Man Glen Zook K9STH would have a heart attack! I have run all kinds of combinations in a pinch, but generally try not to mix. Usually no real problem if you can neutralize and if you dont operate on 10 meters not likely a problem anyway. I have one here that came with a S2001 and a 6146W and it runs fine.

Terry
I also have two KB-1 deluxe vfo knobs,one for the rig and the other on the vfo.
They are close to bronze in color.Wish i had ordered one of ken's limted addition ones.
When you make your posts you put such great detail in them,plus making them in a way that's very understandable and the post you made about using the vfo,instead of the main dial made a lot of sense to me as i had not thought about that before indeed.
Is the turning ratio different on the vfo as it seems smoother.as it has a different feel to it.VFO 230
You are on the money about the tubes as i had to neutralize[still not 100%] as they were doing funny things on ten meters.
I think there would be a good demand for a book on the Hybrids,but as i am more of a visual person You tube would be fine,and think about it you could live forever on there hi hi

Not being worthy to carry your toolbox

Radio Shack cable has had a horrible reputation over the years. The shield is only about 50% braid and leaks RF like a sieve . Belden has held the standard for excellence years, and RS the standard for just the opposite. No, all cables are NOT created equal !

I have two dipole antennas supported by trees .
As you know the trees are going to do what the trees want to do so their has to be a way to prevent your dipole from breaking as the trees move . I went to the hardware store and bought some springs to fix that problem and have never had a dipole snap because of tree movement . One end of each dipole is pulled tight with a spring in line that allows the rope to give as the trees moves . Also I would go with a balanced ,center fed antenna because that's the best way to get the max power to the antenna and the least amount of feed line radiation .Verticals should not be used in areas where their are fences ,houses etc near by because the radiation efficiency is not only dependent on its ground plane near by but other obstacles as much as a 1/4 mile away on a ground mounted vertical. Of center fed antennas like the Carolina windom and the G5RV are really feed line radiators that waste energy so stay away from such antennas . Check out my antenna .I got the wire for next to nothing at a thrift store . I used bamboo poles I found out by the trash to elevate the center part of my antenna , its fed with 450 ohm ladder line from MFJ , a cheap home made 1to 1 balun using a core from Amidon and antenna tuner I won at a Hamfeast .This feed line combo assures me that most of the power gets where I want it to go and that's into the antenna.

Don:

Having original KB-1 knobs are as good as having gold coins based on what I see them go for on Ebay.

I bought two of Kens knobs in the dark shiny bronze.

No the gear train in the VFO 240 is exact same as the gear train in the radio vfo. Just very little or no wear on it. Weak link is the front bushing. It is not a bearing. It is just a press fit into the front metal plate. Some folks "repair" it by disassembly and prick punching the metal around the hole to raise the metal and restore the fit. I think there are pictures of this repair in the Files section. Gordon has had some success by installing a C-cup or bellville washer on the shaft, but this is really addressing axial play and not radial play so much.

I known my responses get long but I hate to just give an answer without some basis behind it. Memorizing the answer is not learning. Ok to accept some things on faith as a novice, but hopefully will not be satisfied with that and will have enough interest to crack open a book.

Carry this thought out with your 2 mtr cushcraft beam mounted above your tribander and fed with 100 feet of good quality Belden RG-58.

Belden 8219
Matched loss = 5.6 dB
Additional loss due to 2:1 vswr = 0.48 dB
Total loss = 6.08
Power in = 100 watts
Power out = 24.7 watts

We fuss a lot about VSWR but note that 2:1 load mismatch only results in approx 1/2 dB additional loss over the feedline loss.

Here is same calc using Belden 8213 (RG-11)

Matched loss = 1.62 dB
Additional loss due to 2:1 vswr = 0.28 dB
Total loss = 1.9 dB
Power in = 100 watts
Power out = 64.6 watts

At 28mhz the total loss with RG-11 would be 0.8 dB or 83.5 watts out with 0.14 dB of the loss due to 2:1 vswr.

At 28Mhz the total loss with RG-58 would be 2.5 dB or 55.6 watts out with 0.3 dB of the loss due to 2:1 vswr.

I did not spend any time looking for Radio Shack RG-58 specs. My guess is probably has more loss per foot, but I do not know that for certain.

Moral of the story is keep feedline loss in mind and put your money in your antenna system and dont go crazy about 1:1 vswr. With right antenna system and 100 watts from your hybrid you can have a lot of fun (assumes good propagation).

Not much more fun than breaking a big gun DX pile up with a barefoot Kenwood hybrid!

43063. Two hybrid questions

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

160 meters on both my 530S and 830S is inoperative. All other bands exhibit full power (100 watts +).
Any idea why?

Are there any tricks or cautions to share about removing the counter board with its fragile fluorescent tube? (The first digit on my 830S contiues its quirkiness, vanishing at times or flashing "0" or "1" alternately and randomly).

Thanks,

Craig

Great information from everybody about the antennas. I do have an Antenna Handbook that my Uncle let me have from about 20 years ago, and he's got all kinds of Post-It notes through the whole thing. I have had so much going on with studying and passing the Tech exam plus lots of other events that I haven't had much time to study any more other than for the General... but since there is such great response on dipoles, I'm going to probably build my own.

I understand the general principles in making a dipole and should be able to do well with it. Now that I have a better feel for how to keep from snapping one, I should be in pretty good shape.

I sure appreciate the feedback and welcome any more. I appreciate all the help, and hopefully soon I'll have the 820 up and rolling to transmit! In the meantime I'm usually calling with the Yaesu between 8 and 11 pm on 28.400 trying to see if I can get anyone to respond.

Barry:

Are you aware there are quite a few low power CW propagation beacons on 10 meters? If you cannot copy these then most likely futile to call CQ if band is not open. With time you will find yourself doing more listening than calling to snag more contacts.

Try listening from around 28.190 to 28.300.

Hi Barry

I had a 40 meter antenna with a 10 meter antenna above it about 5
spacing and both feed independently[RG58],as i don't like tuners.
I got accused of using a linear amp,as i broke a lot of pole ups with my
ts520 barefoot.
As it was my first antenna.i just thought it was just good operating
skills and location.
I forget why i removed my 40 meter antenna,but now my 10 meter antenna
was not performing like it did.
After scratching my head,i came to the conclusion that the 40 meter
antenna was acting as a reflector.
A wire antenna will do the job just fine and there is lots of good books
on the subject.
W1FB'S Antenna Notebook
Wire Antennas by William Orr

Experiment as you maybe surprised at the results you will get.

The late L.B. Cebik, W4RNL, devoted his career to antenna research and experimentation. A website devoted to his work (http://www.cebik.com) is a terrific source of information. Full access does require a paid subscription but I have found it , and several of L.B.'s books, worthwhile.

Would you be surprized if I told you your SWR at the rig, with that antenna, would show much higher (Maybe unacceptable) if you used better quality coax cable ?
It's true, your reflected (as well as the forward) power is consumed by cable loss in the 130 ft of RG58 you mentioned. The result is the low SWR reading at the rig.

Subject: Re: [TS-520_820_530_830] Curious about your antenna setup with Kenwoods

We've been very lucky with a simple G5RV Jr antenna we picked up at HRO
in Salem, NH three summers ago.
We were heading back to Maine from some quick business I had to deal
with in Connecticut and stopped by the store.
The antenna was on special for $25.00 and we couldn't resist.
Once we hooked it up 45 plus feet above ground and running about 130 ft
of coax into the house it gives us 1:8 swr and below on 40, 30, 20, 17,
15, 12, 10 and 6m.
No tuner required using all three rigs: TS-830S, TS-120, Yaesu 897D.
We've made hundreds of DX contacts using 100 watts and a $25 antenna!

Hello to all

I found a ts-830M but the schema provided is that of the TS-830S
there is someone who has the schema of this equipment in high resolution?
(the diagram and the manual found on Internet is difficult to read and you can not see clearly the various links)

thanks for attention

Ugo

I did not mean to infer that you have to use RG-11 or RG-8 or LMR 400 with even lower loss for your first dipole. Many folks use RG-8X (mini) as it is easier to handle. Just wanted to show the affect of line loss as you go up in frequency and to demonstrate that line loss was more of factor than 2:1 swr. Many folks feed their dipoles with good quality 8X and make plenty of contacts.

Belden 9258 (RG-8X) 100 feet

At 14.2 mhz and 1:5 to 1 SWR

Total loss = 1.1 dB

100 watts input = 77 watts output

LMR-400 would only have 0.5 dB loss for 89 watts output

Remember for 1 S-unit on receiving end it takes 6 db or 4:1 increase in power. That means if you have 77 watts output to get 1 S-unit increase on receiving end it would take 4 x 77 or 308 watts out. So a 1 dB loss is not anything to lose sleep over. With a wire antenna that has some modest gain the ERP can more than overcome the 1 dB feedline loss.

If you plan on running power at later date then might want to stay away from RG58 as it is typically rated for around 1000 watts and 8X is around 1500 and 8, 11, and LMR400 all handle 2000 easily.

Terry,
I find that once I install the wave washer, I get rid of both Axial and
radial play to the extent is is almost nonexistent any longer.

Hi Gordon:

Good to hear from you. Well that is great. Not sure how it does that, but take your word for it and certainly much easier to install than prick punching the mounting plate. Maybe if the washer id is pretty close to shaft od then the force of the washer compression prevents shaft from moving up/down and side to side as well as taking out the end play?

Might want to tell folks where you get the washers. I think last one I tried I got out of a brake shoe hardware kit? I think it was metric?

Have not had to repair one in awhile. The last customer I called to ask him if he wanted it repaired by prick punch method stated he had not noticed any problem. It wobbled like it was on an eccentric. I guess some folks have different threshold for what is acceptable. I once borrowed a truck from a friend to haul some furniture and the shocks were so worn I thought I was on a bucking bronco. He apparently hadnt noticed!

Take Care

Topic: 43017 Message: 43075

Hi Terry,

I did what K4EEA described, and you suggested, and read the bulletin you referred to.
But... I've still mixed feelings concerning PROC OFF.

This is what I did. Made a tone generator (circuit diagram
shamelessly stolen from the IC-202S CW side tone generator ;-)
with two settings: 1000 Hz and 300 Hz. (1000 Hz R = 3k48, 300 Hz R= 16k9.
When fed with ca. 5V it generates a perfect sine wave.
With a potmeter I can adjust the output level of the tone generator,
measured on my scope.

MIC GAIN 12 o'clock, 7 MHz, USB.

I followed the variety of adjustment procedures and found out that
the results are similar. Indeed there is a -6dB issue around 300 Hz,
measured at TP2 of the IF-unit.
During the measurements a counter was attached to TP3 of the IF-unit.

With the audio/tone input level used I was able to equalize
the PROC ON and PROC OFF levels with VR7.

But still.. I could not measure more than ~600 mVpp @TP2 with PROC ON.
The AF output of the clipper seems to limit around 600 mVpp
no matter how loud the inserted tone is.
When switching to PROC OFF I can adjust the tone to ca. 2.8 Vpp
before clipping, measured @TP2 on the IF-unit.
Thus, the same as I observed yesterday, now being it more comfortable
as I have a continuous whistle ;-)

Next I did the following measurement: determine how many audio level
is needed in the ring mixer (D26 - D29) to reach maximum output power
(around 90W here). With a 1 kHz tone this amounts 350 mVpp, measured
@TP2 with a scope. With more audio level the TX-chain runs into compression.

This value is around half the value which the RF-clipper generates.
So, that must be okay.

Still I am able to generate 2.8Vpp with in the PROC OFF mode, from
which I conclude that the microphone amp itself produces too much level?

Remco:

I have the covers on my TS-820 at this time, but if needed can remove and make some measurements for you later this week.

What signal level are you injecting at 1Khz into mic line with mic gain at 1200 to produce 2.8v P-P at TP-2? Should not have more than 5mv rms or 14mv P-P from your new tone generator.

How much Carrier Oscillator signal level do you have at CA2 and TP-5?

It should be around 300mv rms. If you can get on the wiper of VR-5 you should see approx 900mv to 1.0v rms of carrier osc signal (amplified by Q17). I know these levels from memory.

This is your Local Osc signal for the Balanced modulator. Normally you want the LO to be much higher than the audio level. 2.8v P-P audio input into the balanced modulator does not seem right to me. Even 600mv seems high to me. Most diode ring modulators see approx 20 db ratio between LO and AF/RF input or approx 10:1 voltage ratio so I guess I would have expected to see something on the order of approx 250mv P-P audio input and approx 2.5v P-P Carrier Osc (LO) input to the Balanced Modulator.

Look at your Carrier Osc levels and I will see if I can find some info on normal audio input level to the Bal Mod in my notes.

We have some other experienced 820 owners who may have this level in their notes?

Well my last step was to put a microphone on the ebay special and try it out.
Output is fine on all bands on cw
When i transmitted on either side band all i got was garble.
I could see output on my power meter,but no audio was heard,just weird sounds.
I can hear myself fine on the monitor position.
The microphone i used was a old tuner mic with a preamp
I had to crank up the preamp high to get output
My mc50 would not work at all.

On cw it is fine except jumps up in frequency by 800 Hz on transmit.

Terry:

I measure around 900 mVpp @TP5/CA2 with my scope (1:1 probe, Z = ~1 MΩ or so,
double checked it just before this writing)
In the service manual I downloaded I see that somebody wrote '0.88V'
next to TP5 thus, naively thinking, that's within range, and I did
not touch T1 on the CAR-1 unit.
However, the same 'service manual' (page 45) states that the 'RF VTVM'
should read 50 mV which converts to 50 * sqrt(2) = 70 mVpp, which
is approx. 13x lower (?)

Concerning your remarks about signal levels/ratios commonly used
with ring mixers, I agree.
Therefore I stated before that I had 'mixed feelings'.

I reached the wiper of VR5, and after keying the TX,
I measure 2 Vpp carrier, which is 2/sqrt(2) = 1.4 Vrms.
Speaking about 'amplification of Q17' ;-)
Thus my levels seem a bit higher than the ones you report, but not
not seriously higher, I reckon.

The measurements on how much audio (1 KHz) has to be injected to
reach full output, measured at the MIC input on the front of the rig,
I will perform later.

The measurement will be done with the same probe and scope
and the MIC input is 'loaded' with 2 kΩ, being the resistance
of the level potmeter of the tone generator.

Now I am curious about signal levels of others @TP2
relative to PROC ON and OFF, in conjunction with full output.

NB. I receive good audio reports, and better reports with the
RF-clipper on. However, when this rig is shipped to the new owner
I want to be sure that everything is in mint condition.

Topic: 43017 Message: 43081

Remco:

50 Mv listed in the service manual is wrong. The radio would not work with Carrier Osc level of 50mv. Some folks think it was a typo and should be 500mv. That is not correct. About the max you can get out of the Carrier Osc by adjusting T1 is approx 450mv. 300mv listed on the CAR board schematic for CA-2 and C1-A at Connector CJ3 is the correct level. Same level for the TS-530 and the TS-830.

I think your O-scope measurements are suspect. Do you have a 50 ohm feedthru terminator or a 50 ohm input on your scope? If so, repeat your readings using 50 ohms termination.

If not scope a VTVM with an RF probe?

I pulled the covers off my TS-820 and I used my Boonton 92E RF Millivolt meter (it is caled) to measure the following:

14.2Mhz
Mic gain at 1200
SG Switch Off
CW mode

1. CA-2 and TP-5 at IF board (TP-5 is back under the side rail). Flip to send = 300mv rms (set on slow side of the peak)
2. I could not get on VR-5 wiper, but could get on R53 47 ohm resistor. Flip to send = 860mv rms
3. I injected 5mv at 1000Hz into the mic jack. Flip to send. TP-2 = 145mv rms.

The .88 volts you see on the schematic is the value from the TX Level Diagram in the Service Manual around page 42. 880mv rms is about as low a LO level that you want to see. Nothing wrong with 1.0v rms level. If LO is too high can have trouble with carrier leakage in the output and if too low then conversion loss can increase. Rule of thumb is you want to see approx 20 db ratio between LO and AF input levels.

For the Balanced Modulator to work you to not want the Audio input signal to be changing the conductive state of the ring diodes. That is the job of the LO. The LO sets the output (IF) frequency pulses and the AF sets the amplitude of those pulses. If you had really had 2.8v P-P audio input into the Balanced Modulator your on air SSB reports would be distorted.

If you do not have a 50 ohm input on your scope or a 50 ohm feedthru terminator that you can use at scope Vertical amp input then connect a BNC tee there and connect a couple of 100 ohm resistors in parallel across the open end of the tee.

If you cant take 50 ohm readings with your scope do you have a VTVM and RF probe? If so take readings with it.

I can repeat the reading using my scope terminated with 50 ohms but the Boonton is very accurate so I am confident my readings are good and what I am use to seeing.

Remco:

Sorry I mis-spoke. I took another look at your readings. No need to take 50 ohm readings.

1. 900mv P-P at TP-5/CA-2 = 900/2.828 = 318mv rms = Perfect Carrier Osc level from Car Osc board.

2. 2 volts P-P at VR-5 wiper = 2.0/2.828= 707mv rms = a little low but not sure how you got on the wiper. What is the bandwidth of the scope you are using? A 20mhz BW scope measuring a 9mhz signal will read approx 6.5% low. Doesnt look like this is reason for 707mv at wiper.

3. Only reading then that is really suspect is the 2.8v P-P at TP-2. 2.8/2.828 = 990mv rms. This should not be possible with 5mv rms input at mic line. Need to make sure you are using 5mv input level signal.

4. With 5mv @ 1Khz injected into the mic jack with Mic gain at 1200 you should see something close to 145mv rms or 145 x 2.828 = 410mv P-P

5. 700mv rms LO signal and 145mv rms audio input to Balanced Mod will work. 140mv/700mv = 20% or 14dB. Ratio is Ok.

Sorry about false alarm. I need to look closer at your readings.

Regarding your comment about getting good reports. It is not uncommon to get get audio reports if the processor is aligned properly and not pushed too hard. In theory it was the best processor that Kenwood put in the hybrids.

Hi Terry,

Thanks for the replies and effort :-)
I also mis-spoke concerning the conversion P-P -> RMS, I should
have added the factor '2', thus RMS = P-P/2.8. Anyway ... ;-)

The scope I use is a Hitachi V-1565 100 MHz scope,
thus for 8.83 MHz I do not suspect the readings.
Please refer to http://i.imgur.com/0rBKQtk.jpg @TP5 IF-unit.
(P10x = 2V, thus 1:1 probe = 0.2V/div -> 4.5 * 0.2 = 900 mVpp,
T-base = 50 ns/div, thus 2.2 * 50E-9 = 0.11 µs = 9 MHz)

About how I got 'on' the wiper: I used a cut off lead from a
resistor, halfway bent in 90 degrees, clamped it in the probe and
pressed it 'under' VR5, after pushing away C83 and L15 a bit.

Concerning the 0.88V I referred to, please look at
http://i.imgur.com/OlTtvk8.jpg (which is p55 b.t.w.) down left corner.
On page 42 I see 0.88V, but it looks like that is on the wiper,
(and measured with a VTVM? thus on the scope it should read 2.8 * 0.88 = 1.76 Vpp).

I do not have a real VTVM. I tried to use my digital multi meter,
but its band width is too low.

Concerning the 2.8 Vpp @TP2, I think I expressed myself wrong:
I do not need 2.8 Vpp audio to drive the rig to full output.
I noticed that, while the clipper output
seems limited to ~600 mVpp (and at this level the rig delivers
full output easily), when switching to PROC OFF I can increase the
amplitude of the audio at the MIC input (on the front) to 2.8 Vpp @TP2
before I measure clipping @TP2. MIC GAIN knob on the front is @12 hrs.

Grmpff, I get confused with all the readings and values ;-)

What I will do is re-re-measure the situation again and describe it
as unambiguous as possible.

Concerning the RF-clipper: yes, that's really an asset. Imho the only
way to give a linear modulated TX the proper punch.

Remco:

The TX Level Diagram readings are all taken with a RF VTVM and are in RMS. So the 0.88 volts shown at the wiper of VR-5 at the Balanced Modulator is 880mv rms read by a RF millivolt meter. 880 x 2.828 = 2488mv P-P or 2.488v P-P on your Scope.

OK scope BW is good and no correction required due to BW limitations.

I will repeat readings using my Scope.

Clever way to get on VR-5 leads!

OK I thought you were reading 2.8v P-P audio level at TP-2 with 5mv 1 khz test signal into mic line.

Yes F= 1/T so 1/.11 x 10-6 = 9.09 Mhz. Close but not precise. Best to use Freq Counter to measure Carrier Osc frequency. My new scope measures and displays frequency on the screen and is pretty close, but I still use my HP counter to measure and set Oscillator trimmers.

I forgot to mention. I would change or cross off the 0.88v at TP-5 on your X-ray board view so not to confuse it with the 0.88v level shown on the TX Level Diagram at the Balanced Modulator.

Of course you know that TP-5 and Wiper of VR-5 are very different levels.

The (58) is referring to page 58 where the Car Osc board schematic is shown and you can see the .3v rms oscillator level. .3 x 2.828 = 848mv P-P.

Terry,

Sorry for the delay, have been down for four days with migraine.

OK following all your steps
1. Antenna on dummy load
> 2. RFG at "5" (need to get a no audio voltage level)
> 3. AFG at "2"
> 4. Mode LSB or USB
> 5. Vox Gain off fully off
> 6. Anti-Vox at Full CW fully CW
> 7. VFO 200, Drive control 1200 OK
> 8. Marker OFF OK
> 9. Measure DC voltage at TP-2 with DMM. Need to wait until voltage decays completely off. Should see +0.001 to -0.001 dcv bouncing back and forth. So essentially zero DC offset voltage at TP-2 with no signal conditions. +0.002 to -0.002
> 10. Now turn on Marker and tune VFO for approx 800hz note and peak Drive control. Watch the DMM and tune the VFO for maximum DC voltage. Should see something like + 0.0305 vdc. Just tune VFO and Drive control for maximum voltage 0.028vdc stable

Let me know what else I can do or what else needs to be checked

>
> I know what it is for a TS-830, but not for a 530 but suspect very close to same as circuits are essentially identical. The reason wanted to get this for Craig was so he could tell if his Anti-VOX circuit is working. Is it producing a DC threshold voltage when there is strong audio signal from Q6 Audio Power Amplifier being coupled to the speaker line ?
>
> At TP-2 there can be two signals. Amplified Mic Audio (ac signal)either from the speaker or your voice and DC "bias" from the Anti-Vox circuit. The Anti-vox essentially establishes

a DC threshold that the mic audio has to overcome in order to key the emitter coupled Schmitt trigger and key the relay. It does this by sampling the output of Q6 speaker line and full wave rectifying it.
>
> Anti-vox circuit samples the Audio Power Amp Q6 output on the Speaker line and is coupled thru the wiper of the Anti-vox pot. It is amplified and then full wave rectified by Q7 and D6/D7. The output from the speaker is rectified and used as a kind of varying "bias" voltage for Anti-vox function based on level of output from Q6.
>
> So the signal I wanted someone to measure was the DC voltage at TP-2 produced when there was no audio from Q6 and when there was a strong audio output tone from Q6 being coupled to the speaker line. I did not state that very well.
>
> One way to do this is to use the Marker signal.

Don,

Check the Audio board connector 7 pin 3 and 5 should have voltage on both, Also check PLL board connector 8 pin 1, should have 9V, if no 9v then your not getting 8.830Mhz on IF board. How is your receive over all?

Don,

When your in SSB does your display change when moving from SSB to CW it should by 800Hz,
What happens to frequency when you change from SSB to tune?

Dave

Dave:

Sorry to hear you have been under the weather. Sure hope you already had covers off a 530 you are restoring to get these readings. I am sure Craig appreciates your help.

Just wanted to give him some idea of dc voltage he should expect to see from Anti-vox circuit with strong signal audio on speaker line from the audio amp output. This DC voltage keeps Q4 turned off until signal from the mic can overide it and turn Q4 on and key the relay.

If he has this voltage he knows the Antivox pot is seeing the audio, the pot is good, and the Anti-vox circuit is working. My guess is that he will not see this dc voltage at TP-2 as Antivox pot seems to have no effect in preventing audio from the speaker being "heard" by the mic and tripping the relay.

Thanks Again for your help
Terry

Should see +0.001 to -0.001 dcv bouncing back and forth.

So essentially zero DC offset voltage at TP-2 with no signal conditions.

+0.002 to -0.002

> > 10. Now turn on Marker and tune VFO for approx 800hz note and peak Drive control. Watch the DMM and tune the VFO for maximum DC voltage.

Should see something like + 0.0305 vdc. Just tune VFO and Drive control for maximum voltage

0.028vdc stable

Hi Dave
Thank you for your reply
The receive is good on all bands
I will check that out plus maybe pull the PLL board again as i might
have missed,bad solder joints
I should have checked it better when i had it off before as i think the
vco pin is lose now.
It's not a big job to remove the boards,it's removing and reinstalling
those connectors that can leed to more problems.

cheers

43094. 830S display problem solved(?)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-26 13:33:47 UTC
From: Craig Roberts
Topic: 43023 Message: 43094

Last night I decided to tackle my TS-830S freq-ish display problem
(that's a joke, son).

The leading digit had been screwy; intermittently flashing "0" instead
of blanking on the 1.5, 3.5, and 7.0 MHz bands and incorrectly blanking
or displaying a "0" intermittently on the 14 and 18 MHz bands.
So, I pulled the Counter Board (very easy to do), cleaned all connector
pins and did a bit of Soder-Wick-ing and re-soldered on several
"iffy"looking joints on the board.

Upon reassembly, I powered up the radio on 40 meters. The normally
blanked first digit flashed "0" momentarily, then corrected itself. All
band displays have been acting normally since, even after repeated
on/off cycles.

We shall see. I am not convinced that the problem will not return, but
hopeful anyway.

Tonight I'll replace R15 and R16 on the Rectifier Board in hopes of
correcting the low power output (1-2 watts) in the TUNE position. I will
hold Terry personally responsible if this does not correct the anomaly :-) .

73,

Craig
W3CRR

Don,

I just went through this same problem a month or so ago, and both Terry and myself got fooled a little when I swapped the IF board out and the fault went away. But the original board when re-installed gave the same fault. The problem wasn't the IF board as the second IF board installed was a later board and had some extra tracks for the 9v. If this fails then we need to look at TIF and work back. If I'm on the wrong track I know Terry and Mike will intervene. Let us know how you go and we can work you through this.

Terry,

Thanks haven't had one for a while so body was just resetting itself. Have the covers permanetly of the 530 and one of the 830s so it is easier to check things as faults pop up. I learnt that from a wise man on this group. forgot it was you who told me thats what you do

Trust your improving and not over doing things?

Don,

You said output is fine on all bands in CW. That tells me the PLL system in CW is working.

You also said you can hear yourself fine with MONI turned ON. That also indicates the speech amp on the AF board is working. If you were to hear garble with MONI turned ON then there would be a problem either in the microphone or the AF board's speech amp but that doesn't appear to be the case.

Is the display showing the transmit and receive frequency in USB and LSB during transmit? If it is then the PLL system appears to be working in both USB and LSB modes.

You said you hear "garble" in USB and LSB. How are you determining this, by using a separate receiver? If so have you disconnected the antenna cable at the separate receiver? If not then do that then test again.

Has this been an on going problem or did it occur when you changed microphones? Do you have another microphone? If so try it with the 830. The 830 has a wide microphone impedance range, 500 ohms to 50K ohms so you can use different microphones.

Have you checked the MC-50 for a broken wire or bad switch?

These are all priliminary test so do the simple stuff first.

Mike
I will try to explain it as i am not the best at putting words on paper
I went on to a local net and he told me he could not hear me,just that
there was something there but not readable.
I also tried talking into it and listing on my other rigs and just some
god awful noise.
My MC50 mic is fine,but no go on the test rig.
The turner mike will show output[watt's] if i turn the preamp up
full,but no audibly speech.
This is the first time i have tried this on sideband as i just got the
output to work because of bad solder joints on the PLL board.

43102. SSB audio/tone generator for adjustments

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-26 14:58:47 UTC
From: hfdxer@ymail.com
Topic: 43102 Message: 43102

A follower of the 'TP2-topic' between Terry and me mailed
for the circuit diagram of the tone generator.

I wanted to make something simple and quick that produces a good
sine wave, and remembered the super simple CW side tone generator
circuit from Icom's IC-202S.

All the info is here: http://i.imgur.com/bcptvkp.jpg

If you replace them without measuring SG voltage at the tube socket in Tune and doing a visual on the resistors for signs of overheating and measure their resistance values before replacing them --I Will Disown You!

43104. TS-520 Low Power

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-26 15:11:57 UTC

Topic: 43104 Message: 43104

I just got my 10 meter antenna in the air and tuned. Tried out my TS-520 tonight. Receives very well. Did the tune up in prep to transmit. Checked power output and external meter shows 70 watts on CW but on USB it bounces up to 10 watts and drops back to 0. If I hold the mic key down it will cycle up and down but no higher than 10 watts.
Any ideas?

I also pulled the cover off the other day to see what filters were installed. It has both the SW and the SSB filters but I see no way to switch off and on. What should I be looking for?

Nice work. I can see you are a homebrewer. Makes me smile.

This is a phase shift RC oscillator. It should look pretty familiar. Take a look at your CW side tone oscillator circuit for any of your Hybrids. On the 830 it is Q1 on the AF board.

Do you have a peak reading wattmeter? Is your mic gain set properly?
You do realize that SSB is Suppressed Carrier? There is no power out unless you are speaking.

70W on 10M CW is about what I would expect.
Were you saying "Ahhhhhhh" into the mic when you were measuring SSB output?
Keying with no voice input on SSB = Zero Watts ! A long "Ahhhhh" will show about 1/4 the Carrier wattage you get on CW. Maybe 20 W at BEST on an average meter.

The 520 is designed to select the CW filter when rthwe mode switch is on CW and the SSB filter on USB or LSB modes. The mode switch has the wiring to do this automaticly.

Don,

Opps, I misspoke! The 830's speech amp is on the IF board, not the AF board. Duh....I was thinking receive amp, sorry for that mistake.

If the MC-50 produces the same good sounding audio heard in the speaker with MONI turned ON as the other microphone does then I don't believe the problem is the microphones or the speech amp on the IF board.

What alignment steps have you use to check and, if necessary, make adjustments to? I don't have the receive and transmit signal path levels but I think Terry, K9TW, may have them.

I apologize for delay in responses, I'm also working on a home brew power supply project for my Heathkit HG-10B VFO for use with my Heathkit DX-40 and Kenwood R599 rcvr setup (see pictures in the group's Photo section under W5RKL).

I concur with John and Dale. Make sure your mic gain is adjusted properly and speak into the mic. You should see the meter move up and back down to near zero. Set the meter switch for ALC and when speaking into the mic adjust the mic gain control but do not exceed the max line on ALC on your voice peaks. Do you have a dummy load? If not you should get one, as you can then check it out and not worry about your antenna set-up. As others said 70 watts CW on 10 meters is about right.

43113. TS-830 Rectifier Unit board

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-26 16:14:59 UTC
From: W5RKL
Topic: 43113 Message: 43113

If anyone has any old non-working Rectifier Unit boards from a 520, 530, 820 and/or 830 hybrid they don't want, I'm looking for them. I'm going to try and design replacement boards so I need the actual boards, the xray pictures in the manuals won't do.

It would be nice if the components, good or bad, along with the board edge connection pins are still on the board. I don't care if the boards work or not as I have no intention on using the boards for anything other than as a guide during the replacement board design process.

I have no intention of spending a lot of money on any board used as a guide.

If you have any of these boards you no longer need then contact me off list.

43114. QRO mod, whaddup wid dat?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-26 16:42:18 UTC
From: Craig Roberts
Topic: 43023 Message: 43114

I'm generally of the "leave well enough alone" and "if it ain't broke, don't fix it"school of thought, so -- NO -- I don't wish to install a QRO mod in my TS-830S. I want to know how to detect one that's been done and how to reverse it.

My radio's been messed with obviously (I found a brass wood screw used for board mounting in one instance) but I don't know to what extent. What components were changed in the infamous QRO mod?

I have rarely seen a "performance enhancing" modification that a) actually works, or b) doesn't degrade performance in another area, or c) is ultimately destructive. I don't mind installing mods that help protect circuitry (like crowbar circuits in power supplies) but, for the most part, I figure the design engineers probably knew what they were doing given their marketing orders and budget constraints.

Oh, the reason I ask is because my 830 wants to load up (yes, into a dummy load) at 300mA or more. On a couple of bands, it won't dip below about 260 mA. I like it down at 220 or less.

Only two more problems to solve and I'll be out of questions!

An external wattmeter is fine, but we still need the original questions answered.

1. Is the meter a peak or average reading meter?
2. Do you have your mic gain set so that the ALC meter is proper?
3. Are you speaking into the microphone when measuring power?

Craig:
I spent months with goofy readouts on a TS 820. They kept changing and coming and going. Terry told me that the counter boards have bad connections, I don't remember if he was referring to the thru hole or the traces, I think both.
I resoldered everything. It still had intermittent problems.Then I did it again and used better wire on the thru hole connections. That finally did it. It works fine for now.
I did find a trace with a hairline crack earlier (I actually used a dissecting microscope to find it) and fixing that helped too.
Terry was correct about the iffy board.

Remco:

Will try to respond in installments. Have some questions. I need to look at readings in RMS as this is how Kenwood lists them and how I take them with Boonton 92e RF millivolt meter.

1.TP-5 900mv is to spec. 900/2.828 = 318mv rms No further discussion.

2.VR-5 wiper 1900mv/2.828 = 672mv rms is low in my experience. Design is approx 880mv rms. Perhaps right angle probe is contacting end of trim pot and not wiper? Not sure would make this much difference? Suggest you take dc CBE voltages at Q17. I will make right angle probe and try to duplicate your reading.

3.QUESTION: I see 0 to 2600mv P-P at TP-2. How are you getting this? Is this done with the Mic gain at 1200 and you vary the output of your test audio oscillator being injected into the mic line? If so, why would you ever inject a audio signal level into the Mic line that would result in 2600mv P-P/2.828 = 919mv rms = nearly 1v rms audio signal at TP-2? In practice with normal operation of the microphone you would never see any signal level remotely close to this high a level. Not sure what you are trying to accomplish with this high a TP-2 level?

4.As we discussed for proper operation of the Balanced Modulator you want the LO to be the higher level signal. You never want the Audio level to be able to control the conduction state of the ring diodes. Rule of thumb for ring diode mixer input signals generally see the LO at approx 1 volt rms and the maximum Audio level at approx 20% of the LO level. I have also seen 20dB as the maximum Audio level. Using 20% rule of thumb 880mv x .20 = 176mv max audio level at TP-2.

5.The highest level of audio test signal that is ever used in aligning a hybrid ranges from 5mv to 10mv. 10mv is used to set the ALC indication to the maximum end of the black ALC box range on the panel meter. Here are my O-scope measurements for TP-2 with these levels of audio injected into the mic line at 1Kz.

5mv = 272mv P-P or 92mv rms
7mv = 365mv P-P or 123mv rms
10mv = 472mv P-P or 163mv rms

Note: With 10mv rms injected into the mic line resulting in approx 163mv rms at TP-2 the ALC indication would be a max of its range and not a recommended place to routinely operate. So not sure why would ever want to see more than approx 163mv at TP-2. Certainly never more than 200mv rms or 566mv P-P. About 25% of what I think you are injecting.

6.With normal speech modulation into the Microphone (five--five ☐five) I would expect to see no more than approx 50mv to 75mv rms at TP-2 (not a sustained whistle).

7.You state that you ended up setting the LO to 451.9khz. I am curious why you did this. The center frequency of the ceramic filter is approx 455khz. If the filters have -6dB bandwidth of 2.7 khz then this would be plus and minus 1.35khz. 455khz minus 1.35khz =

453.65khz. This is why the procedure in the service manual does not work. You cant get any signal into the 455khz filter passband if LO is set to 451.9khz. I have never seen the ceramic filter specs, but suspect very close to the 455khz IF filter specs. Maybe a member has the specs. I have never swept them and should do that one of these days.

That is enough for this installment. We can try to take this in more bite size pieces and perhaps take off the list so we don't bore the non-820 owners?

Craig:

Rather than spend time to describe in detail all the QRO mods that can be done on a TS-830 easiest to just measure 6146 SG voltage. (300 to 210, resistor changes on RF board for driver screen grid voltage, resistor changes on HV rectifier board, ALC time constant changes etc)

Are you comfortable measuring the SG voltage at the tube socket pins of the 6146 finals in RX and TX mode? If so, it will tell you if rig has been QROd. Most common mod is to switch 300 to 210 on the HV rectifier board to increase SG voltage. SG voltage has the most control over IP in a beam tetrode.

I would also measure your 5 ohm cathode meter shunt resistors on the Final board. If they drift high enough the meter will read false high, but typically not this high. Make sure rig is unplugged and HV filter caps discharged. Also allow time for the 300vdc supply filter caps to discharge as there will be voltage on the Final board that can bite you.

If cathode meter shunt resistors are high (I have seen them as high as 7 ohms) replace all four with 20 ohm metal film resistors.

Lastly, does your Plate Tune and Plate Load capacitors behave normally. At or near normal front panel scribed marks?

Gregg:

You might take a look at the INRAD filter alignment procedure that is in the group files section.

The normal procedure for testing power output in SSB is to inject a tone from a audio signal generator at the mike jack and at a certain signal level - usually at 1000 HZ with the mike gain set at a certain level. Then you observe the RF power output and then adjust the signal gnerator frequency above and below 1000 HZ to check the bandpass of the filter and adjust the carrier frequency accordingly.

Good Luck!

Mike
I disconnected the other receiver from the antenna line and i could hear
myself ok
I did the test that Dave said to do and it all checks out ok
I have the Mc50 mic on it and there is no output at all with the mic
gain up full on my power meter.
Seems like there is no mic gain at all???

73
Don/Ve2ud

Check the Audio board connector 7 pin 3 and 5 should have voltage on both, Also check PLL board connector 8 pin 1, should have 9V, if no 9v then your not getting 8.830Mhz on IF board. How is your receive over all?

73's

Remc:

I forgot to ask what you mean about "clipping or compression" with the Processor off. There is no AF or RF clipping or compression with the Processor off other than the ALC action and the ALC time constant in SSB mode. ALC does serves as a rudimentary form of compression, but not its primary purpose. That is why Kenwood included a true RF processor in the rig.

Are you loading the rig in CW mode normally into a dummy load then switching to SSB mode and injecting audio into the mic line from your test oscillator and watching the RF power output on your wattmeter and slowly increasing the gain of the test oscillator until you see no more increase in RF output and calling that point clipping or compression? At the same time you are measuring TP-2 and trying to get that signal level to use to match with the Processor on?

If so, what is the ALC meter doing when you do this procedure? How far do you increase the mic gain and to what ALC meter indication when you see no more RF output on the wattmeter?

If this is what you are doing of course would never run the rig like this.

The way ALC works to prevent overdrive and splatter is as follows:
1. The minute the positive going peak of the RF drive envelope exceeds the negative dc operating bias level on the 6146 control grids grid current starts to flow in the FG lead back to the -C supply return. In SSB this grid current is at an audio rate.

2. At the moment that grid current flows the AGC amp turns on and pulls the ALC bus voltage down reducing the dc control voltage to the TIF amplifier mosfet on the IF board. When the TIF amplifier output is reduced the RF drive to the Driver tube is reduced and the RF drive to the 6146 finals is reduced. The maximum grid current that can flow is limited to approx 40 ua.

3. With the ALC level at approx 1/2 of the black box you will have something on the order of 30 ua grid current and when it reads at far right end of ALC black box range approx 42ua grid current. Any further ALC indication and will be no increase in grid current.

So in theory if you do not talk the rig up beyond the end of the ALC range black box you can not overdrive the rig. You would need a spectrum analyzer to confirm that. I never talk rig up to that point. On the TS-830 you have a separate ALC meter circuit that can be calibrated using 10 mv audio input for the max ALC indication. I talk my 830s and 820s up so I can see some ALC action and nothing more on the Mic gain pot. As I said my guess is that is going to result in something on the order of approx 50mv to 75mv rms audio signal at TP-2.

I am assuming some things about your test procedure and not sure what you are trying to measure and I guess match with the Processor on.

If I am off base I am sure you can correct me.

Hi Don:

Mike is pretty busy and I am drowning! Real quickly are you saying you have good Rf output in CW mode, but no output in SSB mode? Also do you have good audio with the Moni function using the MC-50 mic? In both LSB and USB?

If good Moni audio then you have modulated output at the output of the Q29 TIF amp. It means the mic pre-amp and mic amp circuit is working, the balanced modulator is working. What you do not know is if the TIF signal is leaving the IF board and arriving at the TX mixer on RF board. It should if it does it in CW mode. Should not be a molex connector problem.

Need an O-scope to measure TIF signal at the RF board Conn 7. It is low level. In CW mode approx 35mv to 40 mv P-P. I would probably take a quick look there. If you have TIF signal and no RF output need to see if you have output from TX Mixer and so on until you find where losing RF drive at. In other words need to run TX Level Diagram from TIF to 6146 control grid.

OK

I will think about it some more. Good output in CW mode, good MONI in LSB/USB, but no RF output in LSB/USB.

Tired now and my rigs are all bluring together.

Did you check the mercury vapor rectifiers!

I know that isnt funny. If I think of something will get back to you.

Terry
Nice to see you have a sense of humor too

I did put in the 1.8 ssb filter,but that should not bother it.
The tubes are not matched,but that should not bother it.
Maybe i have inhaled too much lead from soldering?

Don

Update
I just checked into a net and they heard me,but i had to put the
processor on full to be heard.
turning the processor down or off they could not hear me at all

No, too much mercury, from mercury vapor rectifiers. Nasty things ! ! !

43131. Success!

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-27 00:46:30 UTC
From: Craig Roberts
Topic: 43023 Message: 43131

I tacked the 830S's rectifier board for a few minutes this evening with regard to my low, essentially non-existent power output in the TUNE position. Terry nailed it. R15 was open. So, I changed it and R16 while cleaning up a couple of cracked solder joints and desoldering and resoldering the relay, which had not been seated properly.

Bottom line : TUNE now works just as it should with an indicated 15-20 watts out and enough meter deflection to facilitate tuning.

Thanks, Terry.

The only real glitch left is the lack of output on 160 meters. Of course I have never been on 160 meters in my entire ham career, so it's of no real consequence, but it would still be nice to fix the problem.

73,
Craig
W3CRR

Robert, John, Dale & Scott
Thanks for the replies. I have a Watt meter. multimeter, frequency counter and dummy load. The real problem is I forgot that SSB has a suppressed carrier. DUH. I am also a little gun shy after buying so many inoperative radios.
Thanks again

In a message dated 6/26/2013 12:03:23 P.M. Eastern Daylight Time, scottandalene@... writes:

I concur with John and Dale. Make sure your mic gain is adjusted properly and speak into the mic. You should see the meter move up and back down to near zero. Set the meter switch for ALC and when speaking into the mic adjust the mic gain control but do not exceed the max line on ALC on your voice peaks. Do you have a dummy load? If not you should get one, as you can then check it out and not worry about your antenna set-up. As others said 70 watts CW on 10 meters is about right.

Scott, N6CIC

Did rig have good LSB/USB output before changing to the narrow filter?

Did you install it in the original XF-1 position?

Craig:

Unusual for the 160 meter bandswitch position to be bad as you note less commonly used by most owners.

Did you try adjusting L13 and L23? Someone may have cranked them to extreme ends of travel.

Also did you check VCO signal level at TP-3 on 160? Need about 1v rms. If missing check TP-1 on PLL board and adjust T2 for 4.0vdc. See service manual Step 9.

Greg:

I appreciate your concern and buying hybrids off ebay or hamfest is a crap shoot. Even buying from local buyer where you can see it demonstrated is no guarantee especially if you have no experience operating a hybrid.

I note with interest that you posted on another forum the same question. I submit that the answers you got there are worthless.

1."70 watts is normal"--NO IT IS NOT. It isnt horrible but not normal. Could be weak driver tube and/or weak finals. Could be rig just needs good alignment. With more experience you can read the Sect 6 alignment section of your Operating manual and do a good coil pack and IFT alignment and improve both the TX and RX performance. No reason you cannot get approx 80 to 85 watts output from a TS-520 with good tubes.

2."You should get same power out on SSB as you do CW. I own 4 other rigs including 3 Heathkits and they all do" (or some such nonsense)----This is why our ham bands sound like they do as you tune across the SSB portion of the bands and listen to the splatter. Sad.

3."You need new capacitors. Your plate voltage should be around 600 volts"---WRONG. Plate voltage is 800vdc plus keydown. It is common to loose one of the two filter caps which would then result in 1/2 plate voltage or approx 400vdc at tube anode and approx 1/2 RF power output.
You can check this with the HV position of your panel meter. It is not what you are seeing with your TS-520.

4."You need to open up the rig and adjust the ALC"--WRONG. There is no ALC adjustment beyond setting the normal reference level (RF-1) for the ALC bus voltage.

I understand why you would make multiple post regards this problem and you are certainly free to do so to get as much info on your problem as you can, but there is a reason why this forum was created. The challenge is like all Google research you have to be able to sort the good from the just blame bum dope info.

Would you take your Cadillac to the Ford dealership for repair? You could but I would prefer factory trained mechanics, factory service bulletins, and model specific experience.

In summary, if you are loading your rig into 50 ohm dummy load to approx 200ma Ip (plate current) you will be at the 160 watt dc input power rating. At that level you should see approx 90 watts to 95 watts output on all bands with exception of 10 meters where 80 to 85 watts is possible with a well tuned TS520 with good tubes. At this point 70 watts output on 10 meters is nothing to worry about. Getting rig in good state of tune is something you can address with more experience. Just read the circuit descriptions and study block diagram and when you are ready to perform Sect 6 alignments come back if you get stuck. You will also want to do a good internal inspection and we can help you with what to look for and how to do it safely.

As you have been told here in SSB mode you should speak normally into the mic and bring your mic gain up until you see the ALC meter begin to kick up. Your manual tells you to increase mic gain until your ALC peaks are at the max of the rectangular black box. They do this to get little bit of compression. OK to run there, but I would back it down to stay in the middle of the box for less chance of distortion.

At this level of Mic gain your average reading wattmeter will then see peaks from 25% to 33% of your keydown CW power level. So 20 watts to 30 watt max peaks in SSB mode is normal. Your Ip meter will show similar low level Ma peaks.

Again not scolding because you made multiple post on other sites. Just be very careful with the answers you get from these folks. When someone on one of these other sites tells you " I dont own a Kenwood, but my Yaesu XYZ acts like this" or "I owned a TS520 30 years ago and it acted like this" I hate these kind of responses and I suggest you hit the delete key.

I hope with time you will come to realize what a great resource you have on this site and you will come to trust the counsel you get here.
I make mistakes and give wrong info here, but there is a pretty high probability that another member will catch me and correct it. I am member of other sites and I feel strongly this is one of the better radio specific groups there is.

What Dave is talking about is a very low probability fault, but probably merits sharing with all.

Dave experienced only momentary pulse of RF output power due to intermittent pulses of TIF output from the IF board.

We verified that he had signal up to the Xtal filter switching diodes.

We measured the diode switching matrix and verified we had the 8.4vdc to 9vdc voltage present to forward bias the diodes when the Aux relay was keyed. (first thought was bad aux relay contact)

We took a .01 cap and bridged the filter and had TIF output and RF output. Not pretty due to no filter but output none the less.

So our conclusion was we had one or more of the following:
1. Bad Xtal filter or bad solder connections at the filter pins
2. Bad input and/or output filter switching diodes
3. Bad solder connections at the filter switching diodes

What Dave discovered is that he had a very high resistance path in the 9vdc filter switching diode supply. This voltage was there at the filter diodes, but had no current carrying capacity not even 10ma diode forward current capability. We were measuring the voltage with a high Z meter and the meter did not load the 9vdc supply as you would not want it to do for accurate measurement. Here is a case where a old $9.95 analog VOM might have revealed the problem?

The lesson learned is we should have applied 9vdc from a bench supply or 9vdc transistor radio battery in parallel with the rig supply at the filter diode matrix. This would have turned the diodes on and passed signal thru the filter on to the TIF output.

I simply never thought to suggest Dave substitute the 9vdc filter switching supply voltage. Should I ever experience a similar fault condition before I pull the IF board and replace diodes and/or Xtal filters I will remember this radio. You never forget the ones that fool you.

Kudos to Dave for finding the 9vdc fault.

fooled a little when I swapped the IF board out and the fault went away. But the original board when re-installed gave the same fault. The problem wasn't the IF board as the second IF board installed was a later board and had some extra tracks for the 9v. If this fails then we need to look at TIF and work back. If I'm on the wrong track I know Terry and Mike will intervene. Let us know how you go and we can work you through this.

I will tackle the 160 meter output question this weekend when taking other measurements to detect whether or not the radio has been modified.

I am still baffled by the fact that I need to back off LOAD(ing) significantly to hold the power output at 100 Watts/220 mA or so. This is in contrast to my TS-530S.

The 830 is perfectly functional as is and performs very well, indeed. It now looks "mint", so I'd like to act like new, as well.

Thanks for all your help, Terry.

73,

Craig

I changed the filter back to the original one and i now get output very nicely on USB only
The LSB has no output at all
I checked it out on other bands and got the same result
All the ground connections were a bit black i guess from those brass spacers,so took some emery cloth to them.

What is this telling you?

Is the LSB carrier oscillator running?

Have you tried Step 3 of the Service Manual?

TP-3 on IF board provides place to measure LSB Carrier Osc level and frequency. Need 300mv rms level and 8828.50 mhz adjusted by TC-2.

Realize setting TC2 and TC-3 to the frequencies listed in Step 3 is just a starting point. Whereever they are set in RX is how you will sound in TX and vice versa.

Three ways to fine tune TC-2/TC-3:
1. Use the Marker and S-meter as described by Richard Measures in the 830 Survival guide. This works pretty well. Make sure AGC is in Fast and you have delicate touch on VFO to see the meter zero beat quiver. Takes a little practice.
2. Use audio generator and perform Step 30 of the Service manual. This is referred to as setting the Carrier Point. Some say only way to do it correctly. I dont agree with any "only" methods. Some better than others.
3. Use audio spectrum analyzer soft ware and a noise bridge. Spectrogram works great for this. Fun to see your actual passband response and get them matched up.

Adjustment of LSB/USB trimmer caps is little bit personal preference. Have to make sure not set for too much bass as not conducive to good copy in less than ideal conditions and not set for too much treble as audio will sound too thin.

After adjusting suggest you listen to yourself on the Moni.

Terry
I did not try it before the change,as the rig was not putting out,until
i found the solder joint problem.
I am going to put back the original filter and see what happens.

Tks

TS820 worked great when stored 15-18 years ago. Set it up recently at new QTH, various malfunctions when powered on. Cleaned switches, plugs and jacks, relays, etc with contact cleaner. Looked for unsoldered joints etc on swithces.

Now:

cw/usb good on rx and tx all bands.
tune position of mode switch works all bands.
lsb and fsk no audio with rf and af max (faint background hum). If IF shift is rotated ccw 90deg, lsb audio present, but unable to tune for signal that is cipherable.
dig display also goes off in lsb/fsk, returns when IF shift rotated.
Tried adj CAR 1 vr-1, tc-1, and tc-2. No effect.

S meter works great during tuneup on tx,
very very low signal response in rx. Adj vr1-vr2 on IF for zero and max sig with marker, zeroing with vr1 works but unable to obtain s reading with vr2, either on marker or strong revd signal. decreasing RF gain causes meter to move as expected.

Simple problem, simple mind, need help.
Thanks, Jack

Jack:

I think you are on the right track about missing or mis-tuned LSB carrier oscillator. Are you sure you adjusted CAR-1 TC-1 ceramic trimmer? The drawing in the Service Manual is wrong.

If you have a freq counter connect it to TP-5 on the IF board back under the side rail sheet metal at corner of the board. TC-1 LSB ceramic trimmer cap is set kind of deep and not easy to see to get on it. You may want to remove the 2 small screws that hold the cover plate on and then you can see the trimmers labeled as LSB and USB. Also these are pretty touchy if you use a small metal screw driver to adjust. I have a tool with very small thin flat blade set into plastic handle that does not affect the capacitance. So if using a screw driver you most likely will have to make several small attempts to adjust.

I would probably exercise both LSB (TC-1) and USB (TC-2) trimmers several times given how long they have set idle. Then I would adjust them to the IF frequencies listed in the table in the Service manual.

Setting them to these frequencies will get you close, but you will have to do some tweaking and couple of methods to do that I can suggest next.

Ideally you should also measure the rf voltage level at TP-5 and it should be 300mv. If you have a RF probe and VTVM can measure this level or can use an O-scope. If it was set to 300mv when you stored it not likely it has fallen off very much. T1 transformer not as likely to be affected by long idle time like a ceramic trimmer cap would.

Jack:

I forgot to mention make sure you set the Carrier Osc with IF Shift centered and if you tweaked Car 1 VR-1 trim pot you will need to adjust it. You do this in LSB and monitor the frequency with your counter on TP-5 and adjust VR-1 so you get same frequency in RX and TX.

The Saturday's net on 40 meter had 11 stations checking in with poor band conditions. We had 5 new check-in's, N9WQ, N2NTC, KF4EQH, W9PP, and KK4QYS.

Out of all stations checking in, there was:

2 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
1 running TS-830S
1 running TS-900S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 7 stations checking in under very poor band conditions. We had 2 new check-in, W9JW and KB7BRW.

Out of those, there was:

1 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
0 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70

January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39
April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 30, Sunday's total = 27 (Month to date)

Net Info:

43148. Need some quick advice on a totally comatose TS-830S

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-30 21:44:57 UTC
From: synovial_98
Topic: 43148 Message: 43148

Hi,

I am the winning bidder on a (known) dead TS-830S. Allegedly there's no blown fuse or anything burnt. The seller suspects a bad PS. Nothing works, display does not illuminate. Rig was allegedly active until recently.

Here's the obvious things that come to mind:
Open primary winding on the PS xfmr (could be secondary too)
The fuse really is blown - perhaps wasn't verified via VOM.
Verify integrity of the line cord.

Naturally, I'll poke around with the VOM once I get it.

Is there anything else from anyone's experience that I should check?

Thanks in advance for your help.

Regards,
Ken
WB4EJZ

43149. For Remco and Other TS-820 Owners

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-30 21:58:43 UTC
From: Terry Wagoner
Topic: 43149 Message: 43149

Remco:

Got some time this weekend so re-aligned my TS-820 speech processor. Wanted to sweep the 455khz ceramic filters, but my sweep gen only goes down to 1 mhz so I did a rudimentary sweep by peaking the output level at TP-2 and recording that voltage and then moving LO trimmer capacitor TC-4 up and down frequency to the 6db bandwidth points(1/2 voltage level) and recording the frequency of the oscillator at those two points. Here are my results:

Note: I tried alignment with 1000hz, 1200hz, and 1500hz audio injected in the mic line. I ended up using 1200hz for the final setting.

1. TP-2 = 636mv P-P (100mhz scope with 10/1 probe) at 453.3khz with .3mv 1200hz sine wave signal into mic line. (I use a HP3400A true rms AF VTVM to measure output from my function generator)

2. TP-2 = 318mv P-P at 451.9khz and at 454.7khz. This means at the 6dB bandwidth the filters are +/- 1.4khz or approx 2.8khz wide. Using 1200hz audio test signal my low frequency 6dB roll off point was close to 350hz as opposed to 300hz.

3. TC-4 as left setting = 453.3khz (anywhere from about 453.1 to 453.5 seemed to produce about same results)

I listened to my voice using an MC-60 mic and the MONI. I set Comp gain pot for 10dB of compression and 20dB of compression on voice peaks and audio sounded good to my ear at both levels. However, I think I liked the audio closer to 10dB than 20dB. When band conditions improve I will make some contacts on 20 meters and get some reports at various comp gain pot settings.

Perhaps members Robert and Joe both experienced TS820 owners can share their speech processor alignment experiences with you and share where they have TC-4 set.

Clearly the 451.4khz TC-4 LO frequency setting called for in the service manual is wrong. Would result in very low level audio at TP-2.

Terry K9TW

43150. TS-830S dirty relay??

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

One LAST TS-830S glitch (160 meter low output is cured):

symptom: choppy and noisy receiver recovery after transmit

suspect: RL1 on AF Board

Is this likely? Can the relay be cleaned? Replacement looks fiddly but certainly do-able.

Thanks,

Craig

Hi Ken:

Make sure they have not installed an auto fuse.

Download copy of operating manual and service manual.

Ohm meter across line cord and from each leg of line cord to chassis ground = infinity

Ohm meter across line cord with power switch turned on = approx 2.23 ohms.

A good visual is in order. Look at HV filter caps from the bottom. Look at the rupture discs to see if they are bulged or leaky. Can have white crystalline powder at the vent or a brown/black sticky liquid leakage.

Look at HV rectifier board and see if HV diodes appear to be blown or cracked.

Remove PA cage cover and look at large plate choke between the two final tubes for signs of overheating.

Measure the Cathode Meter Shunt resistors on the Final board. Should read close to 5 ohms. There are four 20 ohm resistors in parallel. Sometimes they will physically fracture if finals arc over.

Might want to remove the two 6146 finals and gently shake. Should hear no rattling inside the glass envelopes.

I like to bring up a rig like this on Dim bulb tester to limit fault current and protect your transformer. Can make a very simple one with a line cord and a 120vac lamp socket with pigtail leads. Place the socket in series with the hot leg. Start with a 40 to 60 watt lamp. If it glows brite and does not dim down then have a bolted fault. See internet for plans.

Topic: 43153 Message: 43153

Hello Friends,

Am working on my friend's (4s7WN)TS-830S. The rig has not been used for quite some time. When switched on, I`ve noticed that:

No band noise in RX in any band.
No S-meter indication In RX with antenna
HV position shows 850 Vdc
No ALC. Can not load in any band
Marker signal is very week other than on 40 meters but S-meter is not kicking to marker signal

I cleaned switches, relays,(relay in the audio board sprayed with contact cleaner)pots and band switch twice with `Servisol' and also removed & fixed molex connectors. I've checked the rectifier board and found some resistors were out of tolerance, so replaced R1-R4 and R15 & R16.Thereafter, checked the voltages in all boards. They are with in specs. I removed the VFO, sprayed the rear wiper with contact cleaner and lubed the front bearing with drop of sewing machine oil. I wanted to first try and fix the RX side so removed all valves and powered on.
Now:-
Can hear band noise on 40 meters but on other bands it is very low even if I peak with DRIVE
Can hear the marker signal on all bands but no S-meter response
I can hear broadcasting stations on 40 meters, again no s-meter response.

I injected a signal to antenna connector and also to TP1 terminal on RF broad using my Trio signal generator, S-meter kicks on all bands showing S9 to S9+ level.

I believe band switch is the culprit for low RX. Grateful for any help.

I have a VTVM with a single diode RF probe, Frequency counter,RF signal generator and couple of DMM's and of course schematic & service manual for 830

Thanks
Ravi - 4S6RAV

Hi Ravi:

When you injected RF into antenna connector and TP-1 you say that the S-meter "kicked" to S9 on all bands. Does that mean it spiked or kicked up to S9 momentarily and then fell back to zero or did it go to S9 and stay there as long as you had sig gen connected?

Do you know what level you are injecting from the signal generator? If Marker signal is still very low on all bands it sounds like you have a very high level from your rf sig gen unless Marker is bad which is unlikely. Some of the sig gens are capable of 1.0 volt or greater. You need approx 50uv or -73dBm level for an S9 indication.

If it stays there what does the audio tone from the speaker sound like? Is it normal volume level? Is it distorted?

Do you have another rig that you can inject the sig gen into? If so, do that and set the Sig Gen rf output level for an S9 indication on the good rig and do not move that output level setting. That setting will be close to approx 50uv. Now reinject into the bad rig and see if there is now no S meter indication. If so, then inject at Gate 1 of RF amp Q1. If you now get good audio and S9 indication it is telling you that L41 is bad.

Hi Terry,

Thanks for the reply.

S-meter shows a strength of S9 on all bands and stay there as long as I keep sig.gen connected.Audio tone from the speaker is normal
My sig.genny is Trio SG 402 I guess it is putting out a high level signal.
I have a working 520S.I will inject a signal to it and use the same position of the genny to 830. Will come back.
If antenna transformer is bad,I know there is no replacement but to re-wind it.Am bit nervous of doing any tinny work as my eye sight is not that great due to my age.(54+ now)

Terry: Sorry to worry you again.But thought I'll do the test you said.
I connected sig.genny to my 520se,Here are the results.This is at lowest out put level of the genny.

On 7.200 Mhz and on 3.600 Mhz - S-meter indicating S9+15db- Audio is normal
On 14.175 Mhz - it is full scale (S9+40db) and audio slightly distorted.

I kept the controls of the sig.genny as it is and then connected 830. No indication on S-meter on any band,even the AGC switch set to off,slow or fast.

It is 9 pm here now.So thought to postponed it for tomorrow. If time permits,what I will do is:-
Inject a signal at 8.830mhz with the same signal level to TP-2 on RF board.
Inject a 14.200mhz signal at same level (of course with a DC blocking cap) to TP-4 on the RF board
Will test the Q1 by injecting the same signal at Connection 8 Pin 2
Will measure the Q1 bias voltage at RB1 terminal.

Will come back & share the results.

Thanks
Ravi-4s6rav

Subject: Re: [TS-520_820_530_830] Re: TS-830S,need help

Hi Terry,

Thanks for the reply.

S-meter shows a strength of S9 on all bands and stay there as long as I keep sig.gen connected.Audio tone from the speaker is normal
My sig.genny is Trio SG 402 I guess it is putting out a high level signal.
I have a working 520S.I will inject a signal to it and use the same position of the genny to 830. Will come back.
If antenna transformer is bad,I know there is no replacement but to re-wind it.Am bit nervous of doing any tinny work as my eye sight is not that great due to my age.(54+ now)

Hi Ravi:

When you injected RF into antenna connector and TP-1 you say that the S-meter "kicked" to S9 on all bands. Does that mean it spiked or kicked up to S9 momentarily and then fell back to zero or did it go to S9 and stay there as long as you had sig gen connected?

Do you know what level you are injecting from the signal generator? If Marker signal is still very low on all bands it sounds like you have a very high level from your rf sig gen unless Marker is bad which is unlikely. Some of the sig gens are capable of 1.0 volt or greater. You need approx 50uv or -73dBm level for an S9 indication.

If it stays there what does the audio tone from the speaker sound like? Is it normal volume level? Is it distorted?

Do you have another rig that you can inject the sig gen into? If so, do that and set the Sig Gen rf output level for an S9 indication on the good rig and do not move that output level setting. That setting will be close to approx 50uv. Now reinject into the bad rig and see if there is now no S meter indication. If so, then inject at Gate 1 of RF amp Q1. If you now get good audio and S9 indication it is telling you that L41 is bad.

Topic: 43153 Message: 43160

Is crackling and intermittently weakened signals on reception immediately after T/R changeover most likely caused by a burned relay on the AF Board or a dirty T/R relay next the finals?

Oh -- and what's with that relay on the Rectifier Board? A photo on Charles Socci's site shows the relay absent.

Please pardon my continued ignorance. I will soon know all there is to know about these hybrids. (Yeah, right!) :-)

73,

Craig

I took the 820 to a new ham friend that volunteered to open it up and look to see why it's not transmitting. His tube tester verified this morning that the tubes are fine - and they look to be the original tubes, but he was extremely impressed with how clean and "low mileage," as he put it, this 820 is.

He looked around further and wondered what this mod might be:

http://www.digcservices.com/ham/TS-820-Mod-070113.jpg

He's wondering if this white wire is the culprit now for not being able to transmit. Any ideas on what this mod might be?

Thankfully he did verify that nobody did a CB mod, so that's great. So far things are looking pretty good - with my extremely limited knowledge I'm obviously relying on others that know the 820 for more help, so thanks in advance for any insight.

Ravi:

Is the generator a SG-402? Are you saying level being injected is with switch to Low position and the Gain pot full CCW? Do you have the manual for this generator? What does is say about the output level? I have never owned or operated this model. This style generator often has very high leakage and what you may be seeing is signal not coming down the test lead, but being radiated and picked up by your TS520SE.

In any event you know that with your TS520SE you get speaker audio and high S-meter indication with the generator set to its lowest level and get nothing out of the 830 with this same level injected.

Yes make sure to use DC blocking/coupling cap. Keep us posted of your progress. Should be pretty easy to isolate the problem with signal injection. I hope it is not L41. Need good eyes and steady hands otherwise end up breaking lots of hair fine wire!

Here is reminder about levels you will need injecting at Conn 8 Pin 2 vs directly at Gate 1 of Q1. These are from my TS830 notes with 14.200 mhz signal and Drive control peaked at 1200 and RF gain pot full CW and VFO tuned for max S-meter indication on USB.

1. Inject 50uv or -73dBM at SO-239 = S9
2. Inject 50uv at Conn 8 Pin 2 = S0. It will take approx 5mv or -33dBm signal level at Conn 8 Pin 2 to get S9 indication.
3. Inject 50uv directly at Gate 1 of Q1 = S7. It will take approx 500uv or -53dBm signal level injected directly at Gate 1 of Q1 for S9 indication.

You are no bother. Keep us posted.

Hi all! I am new to the group. I just purchased one of these fine rigs and am trying to troubleshoot the above mentioned problem. Since I went to tech school in the 70's, I am a little out of practice in the troubleshooting of discrete components. Would someone be kind enough to
tell me if this is a common issue with these rigs? I read something on the web that leads me to believe that the AGC may be involved.

Any and all information will be greatly appreciated.

Tom

43166. Re: TS-830S RL1 or RL1 (or RL1)?

Topic: 43153 Message: 43166

Craig:

1. Ordinarily I would not recommend replacing components that are not broken, but I make exception with RL-1 on the Audio board and the HV filter caps. RL-1 because it is source of many intermittant problems and cleaning contacts is not easy and not a long term fix. Also may come a day when cannot find a replacement. Today you can buy a NOS replacement from Ken K4EAA and from Jim at HybridRestore. I would change it out. With the HV caps when they go they can cause collateral damage (hv rectifier diodes) and can make quite a sticky mess to clean up.

2. I believe Charles Socci is showing a TS-530 and it does not use a relay contact to switch -C voltage to the 6146 finals screen grids when the SG switch is in the OFF position in RX mode. This negative voltage makes sure the finals are cut off. By the way I dont believe this relay is available anymore either. Fortunately contact does not see any current so relay should last long time. Perhaps others know of a source for one? It is an Omron G2e. I have used spares I bought from Bob Mansker.

Tom,

first...check the "why didn't I think of that?"...make sure that the RF gain control is turned full right, or clockwise...if it's turned full ccw the meter will go full swing and you
won't hear anything. Also, a cause of "deafness"...is a missing "shorting plug" on the rear 9 pin socket...but, that should not make the meter peg out.

  Happy 4th of July....UP with the COLONIES!

Well that is good. Yes probably time to button up and get it on the air. After all we do buy them to drive them.

Someday when you get bored you can pull it down and start on Step 1 of the service manual alignment steps and go thru it. It will be a learning experience for you and typically can find some areas for performance improvement. The steps are pretty good with no gross errors, but some can use some help. I consider a gross error is when wrong test point is called out, wrong adjustment component, and wrong acceptance criteria all in one step. This is a no joke if you ever try to use the 820 service manual.

Enjoy this fine radio. Will always be those who like the 820 better and those who like the 830 better. Best is to own one of each. I lean to the 830 and have two full filtered ones as well as a TS-820.

Hi Joe:

A good question that had to be asked. Not many of us who have not had some kind of operator error. OK as long as it does not result in a crash and burn! Couple of more questions for Tom.

First of all welcome to the group.

1. What happens if you turn AGC to OFF?

2. Do you have the service manual and schematic?

3. How familiar and comfortable are you working inside the radio and taking voltage readings? If so, need to measure RF-1 at the IF board. If it is in the 3.3 to 3.5vdc range that is good. If it is very low or missing report back for further direction.

4. You can also try jumpering AGL and AGC terminals at Connector IF-3 at the IF board. If radio comes alive then remove and clean the Aux Relay contacts. Wet copy paper with DeOxit and pull thru the contacts with lite pressure on the armature. Make sure you clean the NC (normally closed) contacts. If this works you may want to consider buying a replacement relay while they are still available.

Tom:

This may be obvious to you.

I forgot to mention any time you jumper anything in the radio you must be 125% certain you are on the right points. Especially important if doing this with the rig powered on. If any doubt in your mind just go ahead and pull the Aux Relay and clean the contacts. It might not resolve your problem, but wont hurt to clean it and no risk of damage from jumpering wrong terminals.

Thank you for all of your replies.

I noticed that the meter switch has no effect on the meter, it remains pegged until I switch the power to OFF.

AGC SLOW FAST OFF has no effect.

I have downloaded the service manual and schematics.

I will remove the covers and make some voltage measurements soon. I have a disability that slows me down a bit.

Hi Joe:

A good question that had to be asked. Not many of us who have not had some kind of operator error. OK as long as it does not result in a crash and burn! Couple of more questions for Tom.

First of all welcome to the group.

1. What happens if you turn AGC to OFF?

2. Do you have the service manual and schematic?

3. How familiar and comfortable are you working inside the radio and taking voltage readings? If so, need to measure RF-1 at the IF board. If it is in the 3.3 to 3.5vdc range that is good. If it is very low or missing report back for further direction.

4. You can also try jumpering AGL and AGC terminals at Connector IF-3 at the IF board. If radio comes alive then remove and clean the Aux Relay contacts. Wet copy paper with DeOxit and pull thru the contacts with lite pressure on the armature. Make sure you clean the NC (normally closed) contacts. If this works you may want to consider buying a replacement relay while they are still available.

Tom:

The panel meter will function as an S-meter in receive mode at all positions of the meter select switch. The other positions only indicate the respective parameter in transmit mode (rig keyed).

OK about no difference with AGC off. Sometimes meter will peg in Fast and Slow and be OK in OFF. There is a reason for that and pretty easy fix but no need to go into detail as not your problem.

Hopefully it will be simple as bad Aux Relay contact.

Be very careful as radio has exposed high voltage points that can hurt and maybe kill you.

I am thinking pulling the Aux Relay and cleaning it with rig off and unplugged is a good first step for you.

Terry,

Many thnaks for the troubleshooting advice.

Operating/service manual and the "TS-830 Survival Manual" has been downloaded, VOM warmed up - just need the radio now!

Regards,
Ken

Subject: [TS-520_820_530_830] Re: Need some quick advice on a totally comatose TS-830S

Hi Ken:

Make sure they have not installed an auto fuse.

Download copy of operating manual and service manual.

Ohm meter across line cord and from each leg of line cord to chassis ground = infinity

Ohm meter across line cord with power switch turned on = approx 2.23 ohms.

A good visual is in order. Look at HV filter caps from the bottom. Look at the rupture discs to see if they are bulged or leaky. Can have white crystalline powder at the vent or a brown/black sticky liquid leakage.

Look at HV rectifier board and see if HV diodes appear to be blown or cracked.

Remove PA cage cover and look at large plate choke between the two final tubes for signs of overheating.

Measure the Cathode Meter Shunt resistors on the Final board. Should read close to 5 ohms. There are four 20 ohm resistors in parallel. Sometimes they will physically fracture if finals arc over.

Might want to remove the two 6146 finals and gently shake. Should hear no rattling inside the glass envelopes.

I like to bring up a rig like this on Dim bulb tester to limit fault current and protect your transformer. Can make a very simple one with a line cord and a 120vac lamp socket with pigtail leads. Place the socket in series with the hot leg. Start with a 40 to 60 watt lamp. If it glows brite and does not dim down then have a bolted fault. See internet for plans.

Ken:

OK --My radios are all blurring together so if you need any more help please give a short reminder of the symptom along with what you have done so far to resolve the issue. I think talking about the blown fuse rig.

At some point you can read the circuit descriptions (could be developed out more but better than nothing) and follow along on the block diagram to start understanding how the radio works. Troubleshooting will start your familiarity with layout and locations,test points, adjustment points etc.

Suggest you download the Loading instructions from K4EAA site. His instructions amplify on the instructions in the manual.

Hi All
Just a update on my problem with no LSB output
I did the carrier balance adjustment on the if unit as per the
manual.
It said to adjust tc2 and trimpot vr4 alternately.
Adjusting vr4 did nothing,so i tried keying the mike and adjusting vr4
and tc2 and was able to get output.
The alc meter was not kicking as high as USB was,so i just cranked up
the mic more on LSB and i got good signal reports.

I think one of my tubes has gone kaput.
I now have no ip reading and the bias test,will only yield 150 ma's full
I get only 50 watts out,half the power and half bias output

As i have to get some new tubes i will wait until i get them before
doing any more test's with those mixed tubes.
In the meantime i am trying to custom fit a DS1 convertor on it as i
don't have a DS2
Wish me luck as i will need it

Hi Terry,

Thanks for the information from your notes.

Yes, it is a SG-402. I have the manual some where with my other books. If I can remember correct, out put is around 1vdc max. But when I checked with a RF probe & DMM. max it gives is 860 milivolts.

Let me give you the results of my tests to-day.I can not go down to micro volts range in my sig.gen

Connected my freq.counter to the sig,gen and adjusted to 8.83Mhz. Measured it's out put level with RF probe/DMM. The lowest I can go is upto 8 milivolts.Beyond that freq.counter does not read.So with that level of signal:-

1. Injected 8.30Mhz/8milivolts signal to TP-2 - No s-meter indication either on fast or slow But audio was good (AF gain control at 9 o'clock position & RF control fully CW). When I rotate RF control to 12 o'clock position,s-meter goes up and stay & audio is low (which is normal I believe).

2. Then injected 14.200Mhz/8milivolts signal to TP-4 via DC blocking cap - Results are same except audio was very slightly distorted

My thinking on above tests is that IF chain is good,product detector & AF amp are OK but have a question on AGC bus voltage.

3. Injected the same signal as 2 above to RB1 terminal.- Low audio even peak with DRIVE. No indication on S-meter.When I move the RF gain control to 12 o'clock position,no audio at all. (does this means Q1 device is bad?)

In all above tests,I kept the AF gain control at 9 o'clock position,RF control fully CCW and MODE at USB..

4. Then I checked the voltage at RB1 -connection 8 Pin 2 terminal with a DMM and it reads 1.03V and -3.28V when SEND switch flip up.-Does this means RL-1 relay contact is good and dc bias on Q1 is OK?

5. Injected a 8milivlots signal at TP-1 terminal and checked all bands peaking with DRIVE. Audio is good except in 1.5Mhz band where it is low.

Is the problem with L41 or D2 on RF board?

Appreciate your help.

Subject: [TS-520_820_530_830] Re: TS-830S,need help

Ravi:

Is the generator a SG-402? Are you saying level being injected is with switch to Low position and the Gain pot full CCW? Do you have the manual for this generator? What does is say about the output level? I have never owned or operated this model. This style generator often has very high leakage and what you may be seeing is signal not coming down the test lead, but being radiated and picked up by your TS520SE.

In any event you know that with your TS520SE you get speaker audio and high S-meter indication with the generator set to its lowest level and get nothing out of the 830 with this same level injected.

Yes make sure to use DC blocking/coupling cap. Keep us posted of your progress. Should be pretty easy to isolate the problem with signal injection. I hope it is not L41. Need good eyes and steady hands otherwise end up breaking lots of hair fine wire!

Here is reminder about levels you will need injecting at Conn 8 Pin 2 vs directly at Gate 1 of Q1. These are from my TS830 notes with 14.200 mhz signal and Drive control peaked at 1200 and RF gain pot full CW and VFO tuned for max S-meter indication on USB.

1. Inject 50uv or -73dBM at SO-239 = S9
2. Inject 50uv at Conn 8 Pin 2 = S0. It will take approx 5mv or -33dBm signal level at Conn 8 Pin 2 to get S9 indication.
3. Inject 50uv directly at Gate 1 of Q1 = S7. It will take approx 500uv or -53dBm signal level injected directly at Gate 1 of Q1 for S9 indication.

You are no bother. Keep us posted.

>
> Do you know what level you are injecting from the signal generator? If Marker signal is still very low on all bands it sounds like you have a very high level from your rf sig gen unless Marker is bad which is unlikely. Some of the sig gens are capable of 1.0 volt or

greater. You need approx 50uv or -73dBm level for an S9 indication.
>
> If it stays there what does the audio tone from the speaker sound like? Is it normal volume level? Is it distorted?
>
> Do you have another rig that you can inject the sig gen into? If so, do that and set the Sig Gen rf output level for an S9 indication on the good rig and do not move that output level setting. That setting will be close to approx 50uv. Now reinject into the bad rig and see if there is now no S meter indication. If so, then inject at Gate 1 of RF amp Q1. If you now get good audio and S9 indication it is telling you that L41 is bad.

Don:

You should not be adjusting TC-2 and VR-4 for LSB output. Is this a typo? You adjust VR-4 and TC-3 for Balanced Modulator carrier suppression or null.

This is done after completing the SSB Frequency Response adjustment detailed in Step 30. Some call this step the Carrier Set Point adjustment. Here you will be setting both the LSB and USB Carrier Osc trimmers to set the 3dB roll off to the factory recommended low and high audio frequencies.

To do Carrier null I connect a Pl-259 connector with two 100 ohm resistors in parallel across the center to shell to the rig SO-239. You can measure across this small 50 ohm dummy load with your RF probe/VTVM, RF millivolt meter, or O-scope. You alternately adjust VR-4 and TC-3 for lowest RF voltage. You do it in LSB and USB until you get about same low level of rf voltage in each mode. Have to go back and forth multiple times for best balanced null. Not possible to get a complete null. Another way that works pretty well is to set another receiver next to the rig and tune to same frequency and listen to the null. See Step 29.

Regards Step 30 you do this at 50 watts because you will be having longer than normal keydown times to adjust TC-2 LSB and TC-3 USB trimmer caps at 300hz and 2700hz. Limiting the power to 50 watts keydown with 5mv to 7 mv audio injected in to the mic line is easier on the Final tubes. You will adjust the respective trimmer until you see approx 25 watts at each frequency which represents the 3dB roll off points.

Your statement about having no IP makes no sense when you say the bias test only produces 150ma. If you can read 150ma then you have Ip. When you say "bias test" are you saying you are varying the bias voltage pot for maximum plate current and watching IP to see if it holds? If so, have to be very careful doing this test. Have to make sure you have a good clean smooth bias pot and never exceed 300ma for just a couple of seconds. I dont recommend this test for average person.

It is possible you have damaged a final tube. Also, what is your plate voltage doing. If you have lost a HV cap can also have half power output.

43180. TS-820S -- recently repaired, possible alignment necessary?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-02 16:47:27 UTC
From: w3drk
Topic: 43180 Message: 43180

I recently came into position of a TS-820S with a fried transformer and considerable damage the finals (burned chokes and cathode resistors) and it somehow managed to fry the plate current multiplier resistor (meter still OK) and damage to the BIAS switching on the RF board as well.

The transformer has been replaced, I repaired the finals, new old stock RCA 6146Bs and driver, and after replacing a few fried resistors and an open transistor on the RF board, it seems to receive and transmit well with one exception. The when peaking the receiver with the drive control, its nowhere near peaking the ALC deflection when transmitting. And when transmitting on 20 meters the drive is fully clockwise but hasn't peaked. The behavior is similar with the screen off when neutralizing and watching RF output on a scope...on 20 meters the output from the driver never peaks even with drive fully clockwise.

Am I right to assume it may be necessary for me to walk through Clif's "Simplified and quick alignment" procedure? Before I touched the alignment I figured I'd best check with the Hybrid experts first. Unless someone was tinkering with the cans or swapped the RX board from another radio can't imagine the alignment would be so far out...perhaps there is a damaged component I may have missed that's affecting the alignment?

By the way, 9v from the AF-AVR board is a solid 9v.

Any tips? Safe to proceed with alignment or any other suspect damage I should be looking for first?

Thanks!
Dieter - W3DRK

43182. Lessons learned

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-02 17:46:40 UTC
From: Craig Roberts
Topic: 43165 Message: 43182

This is primarily aimed at newbies -- like me -- who have just joined the Kenwood hybrid community.

I am a convert. As proof of my new obsession, I have now purchased three hybrids - two TS-530Ss and a TS-830S. One of the 530s is in the expert hands of Jim Showker. The radio was essentially unused in mint cosmetic condition and still in its original, unmolested boxes when I obtained a month or so ago. And that was the problem. Decades of disuse rendered the radio pretty much inoperative due to tarnish and corrosion on connectors and contacts. Jim and his boys are bringing it back to life now.

Although I have no regrets whatsoever about sending my mint prize to Jim, I now realize that I may very well have been able to resurrect this radio myself (although, admittedly, I don't have the nifty lab gear -- sweep generator and such -- to do the very best post-service alignment possible.

I worked on the other two radios personally with the invaluable aid of friends on this reflector and have both Kenwoods working very nicely now. The quality of their construction makes repairing these wonderful radios a fairly painless task. Here are some lessons learned from my experience:

* Firstly, do NOT be offended by the oft-repeated advice to unplug your radio, let it sit idle for a spell and then discharge the HV components through the top of the plate choke in the finals cage before poking your fingers into or even near the machine's innards. Your friends are not assuming you're an idiot or careless when they pass along this counsel -- they're genuinely concerned about your welfare. It never hurts to be reminded. It does hurt to be bitten by 800 volts (though not necessarily for long).

* It has been recommended that the HV caps should be changed out as a matter of course upon receipt of your new/old hybrid (unless the previous owner has done so). Jim Showker and Ken Kemski both sell HV cap replacement kits that include the attendant resistors and caps. The job is easy and serves as a good introduction to the bowels of the radio.

* As has been mentioned time and time again, MOST problems from stock hybrids (unmodified or otherwise not messed with by previous owners) are due to tarnish and corrosion. The primary suspect is the band switch, the bane of nearly all older rigs, thanks to their vulnerability and mysteriously delicate construction. A gentle, thorough cleaning of all wafers, including those in the finals cage,

cures many ills. DO THIS FIRST (unless your radio's working okay to begin with).

* The same goes for the circuit board plugs and headers (if you think these Kenwoods are bad about this, try working on a Drake TR-7). Unplug them gently, wipe the headers with a contact cleaner moistened Q-Tip and replace the plugs. Some of the plugs are in awkward places for hammy fingers to grab. I use a pair of needle nose pliers with plastic tubing slipped over the tips to extract these plugs. I haven't killed one yet.

* Relays are another vulnerable component. The antenna relay next to the finals on the underside of the radio (hidden by an easily removable metal shield) is subject to corroded or tarnished contacts. This can lead to "iffy" recovery in the transmit/receive cycle. The relay is a plug-in device (hooray!) and can be removed readily. The unsealed plastic cover can be snapped off (gently work the little tabs on either side of the base) and the contacts cleaned with a thin strip of paper moistened with contact cleaner. Don't be tempted to burnish the contacts with an abrasive of any kind - you'll do more harm than good). A replacement relay is available if yours is shot or damaged for some reason (possibly abused by a sandpaper wielding former owner).

* If cleaning the antenna relay doesn't clear up your T/R problems (like receiver noise and slow recovery or intermittent signal attenuation), you may need to replace the pretty much unserviceable RL1 on the AF Board. (Again, replacements are available from Ken Kemski and Jim Showker). This task looks a LOT more daunting than it actually is. Getting to the underside of the AF Board is simply a matter of undoing the screws that hold the frame surrounding the board itself to the chassis and unscrewing a ground lug connection to the chassis at the rear of the board. No unsoldering of wires connected to the board is necessary and you probably don't need to unplug anything (though I did to clean the headers, etc.). You can simply flip the frame and board assembly over and go to work with your desoldering tool or, in my case, 25 watt miniature iron and Soder-Wick. It took less than ten minutes to remove the old relay and install the replacement. The result was dramatic. Not only did my T/R problems disappear, the receiver audio actually sounded considerably better. Who knew?

* One other repair that I performed on my TS-830S was necessitated by a total lack of drive in the TUNE position. Our resident guru, Terry, suggested the problem might lie with R15 and/or R16 -- screen voltage dividers on the Rectifier Board. I tested them and, sure enough, R15 was open. I replaced both -- just 'cuz I was there -- and the TUNE function sprang to life. I am told that this problem is not altogether uncommon. Once again, access to the underside of the affected board was simple and the component replacement task quick and easy.

I will confess that I was shy initially about working on these radios myself. Sure, I have restored to as-new condition such densely packed beasts as the Hallicrafters SX-28 and SX-42 receivers, the Hammarlund SP-600 and the Collins R-388. For whatever reason, though, I thought the Kenwoods -- totally foreign to me (yuk-yuk) -- would be at least as intimidating. I was wrong. The TS-530S and TS-830S (and, I suspect, the 520 and 820) are a joy to work on. Their modular construction and excellent build quality make most service tasks, if not always dead simple, at least doable by the average guy who can harmlessly wield a screwdriver, needle nose pliers and soldering iron.

Best of all, once you're done fiddling you'll end up with a truly wonderful radio.

SINCERE THANKS TO JIM, KEN, TERRY AND ALL OTHERS WHO HAVE ENCOURAGED AND COACHED ME. I'll probably be back with more mysteries and queries before long, but I've learned a lot thus far, thanks to y'all.

VY 73,

Craig

Terry

Yes it is a typo error as i am using the original manual that came with this rig,and i went and got another manual to check against it and sure enough,it said TC-3 and not TC-2.

I went to adjust the drive coils and i think the tube went puff as the fuse blew.
I replaced the fuse and thought all was ok until i tried to load the rig.
I could get my 60ma ok and good ALC reading,but when i went to dip the plate there was no reading at all.
I did the tube test by-----Testing Tubes, a previous post by Bill, K0ZL,and only got 150ma full adjustment and it should read at least 200ma.
I also did the tube tests for shorts,but did not find a problem using the method by Walt N9WB
HV test was about 850 watts
Hard to start this tech stuff very late in life.but on the other hand i think i have more fun learning this side of the hobby instead of just being a DX chaser.

Topic: 43153 Message: 43184

Ravi:

1. Injected 8.30Mhz/8milivolts signal to TP-2 - No s-meter indication either on fast or slow But audio was good (AF gain control at 9 o'clock position & RF control fully CW). When I rotate RF control to 12 o'clock position,s-meter goes up and stay & audio is low (which is normal I believe).

My Response:

Yes rotating RF GAIN pot from full CW to 1200 should produce upscale movement of the S-meter. Should have approx S8 TO S9 indication at 1200 position of RF gain pot.

No reason to test any further back from TP-2 on the RF board. Assuming Conn 5 and its solder connections are good then problem has to be on the IF board. Q1 and L41 have nothing to do with substitute 8mv RIF signal not producing S-meter indication.

Injecting 8mv @ 8.830mhz at TP-2 should produce approx 30 over S-9 S-meter indication.

Do the following:

1. Measure RFG voltage at Conn 6 on IF board. With RF gain pot at full CW position should read approx 3.6vdc.

2. CAUTION: Measure AGC voltage at Conn 15 Pin 3 brown wire. Do not rely on the brown wire. Make sure you are on Pin 3 and not Pin 1 where there is 300vdc present. Depending on input Z of your meter the AGC bus voltage will read low and drive the S-meter up scale. A 11meg VTVM will read approx 3.0vdc and S meter will read S4 to S5.

3. If above tests are all good then inject 8.830 at IF board as follows:

A. At IF board Conn 6 pin 6 inject 8mv @ 8.830mhz and see if S-meter comes alive. If it does, the problem is between Conn 6 on IF board and Conn 5 on RF board. If it does not, then need to move down the IF chain injecting until you find where it is being lost. Problem is there are not many good test points in the path.

B. Go to IF01 on rear panel and inject same 8mv @ 8.830mhz. If comes alive then problem is with Q1 RIF amp. If it does not then move down to the filter switching diodes and inject there. Once you get past Q2/Q3 Mixer will have to change frequency to 455khz.

Lastly, are you certain you have an 8mv signal? Can you inject into a known good rig? Another hybrid would be good. 8mv @ 8.830mhz into the coax connector on rear panel will give approx S4 to S5 indication and using 14.2mhz @ 8mv will give approx 40 over S-9 indication.

Don:

As I said I do not recommend the K0ZL tube test. I had forgot it was in the files section. If it were up to me it would not be there.

As I mentioned you better have a good clean smooth bias pot. It only takes a moment to have finals glowing red hot and be destroyed as you move this pot for first time perhaps in years into uncharted waters.

What is wrong with setting the resting plate current to 60ma and then loading rig into a dummy load to 100 watts output and then reading plate current? If you can do that at approx 225ma Ip your finals are fine. A much safer and controlled test and not DC static test, but a dynamic test with RF drive as the tubes will see in real operation.

Just my opinion.

Craig,

  Your comments are well appreciated. I too, was a "newbie" a few years ago. Several members of this board helped me over come some...ok...a lot of ....."lack of knowledge." I am still no where near as good as Terry(k9tw), Mike(w5rkl), or Gordon(n6wk). I try and help where I can. Glad you got the ol' girl workin'. Hey...I still have a scar on my fore arm where I got "bit" by some RF volts...'cause I was in a hurry...won't do that again. That's why me, and others warn about discharging voltage.

  Happy 4th of July....UP the the COLONIES!

73 Joe

Subject: [TS-520_820_530_830] Lessons learned

This is primarily aimed at newbies -- like me -- who have just joined the Kenwood hybrid community.

I am a convert. As proof of my new obsession, I have now purchased three hybrids - two TS-530Ss and a TS-830S. One of the 530s is in the expert hands of Jim Showker. The radio was essentially unused in mint cosmetic condition and still in its original, unmolested boxes when I obtained a month or so ago. And that was the problem. Decades of disuse rendered the radio pretty much inoperative due to tarnish and corrosion on connectors and contacts. Jim and his boys are bringing it back to life now.

Although I have no regrets whatsoever about sending my mint prize to Jim, I now realize that I may very well have been able to resurrect this radio myself (although, admittedly, I don't have the nifty lab gear -- sweep generator and such -- to do the very best post-service alignment possible.

I worked on the other two radios personally with the invaluable aid of friends on this reflector and have both Kenwoods working very nicely now. The quality of their construction makes repairing these wonderful radios a fairly painless task. Here are some lessons learned from my experience:

* Firstly, do NOT be offended by the oft-repeated advice to unplug your radio, let it sit idle for a spell and then discharge the HV

components through the top of the plate choke in the finals cage before poking your fingers into or even near the machine's innards. Your friends are not assuming you're an idiot or careless when they pass along this counsel -- they're genuinely concerned about your welfare. It never hurts to be reminded. It does hurt to be bitten by 800 volts (though not necessarily for long).

* It has been recommended that the HV caps should be changed out as a matter of course upon receipt of your new/old hybrid (unless the previous owner has done so). Jim Showker and Ken Kemski both sell HV cap replacement kits that include the attendant resistors and caps. The job is easy and serves as a good introduction to the bowels of the radio.

* As has been mentioned time and time again, MOST problems from stock hybrids (unmodified or otherwise not messed with by previous owners) are due to tarnish and corrosion. The primary suspect is the band switch, the bane of nearly all older rigs, thanks to their vulnerability and mysteriously delicate construction. A gentle, thorough cleaning of all wafers, including those in the finals cage, cures many ills. DO THIS FIRST (unless your radio's working okay to begin with).

* The same goes for the circuit board plugs and headers (if you think these Kenwoods are bad about this, try working on a Drake TR-7). Unplug them gently, wipe the headers with a contact cleaner moistened Q-Tip and replace the plugs. Some of the plugs are in awkward places for hammy fingers to grab. I use a pair of needle nose pliers with plastic tubing slipped over the tips to extract these plugs. I haven't killed one yet.

* Relays are another vulnerable component. The antenna relay next to the finals on the underside of the radio (hidden by an easily removable metal shield) is subject to corroded or tarnished contacts. This can lead to "iffy" recovery in the transmit/receive cycle. The relay is a plug-in device (hooray!) and can be removed readily. The unsealed plastic cover can be snapped off (gently work the little tabs on either side of the base) and the contacts cleaned with a thin strip of paper moistened with contact cleaner. Don't be tempted to burnish the contacts with an abrasive of any kind - you'll do more harm than good). A replacement relay is available if yours is shot or damaged for some reason (possibly abused by a sandpaper wielding former owner).

* If cleaning the antenna relay doesn't clear up your T/R problems (like receiver noise and slow recovery or intermittent signal attenuation), you may need to replace the pretty much unserviceable RL1 on the AF Board. (Again, replacements are available from Ken Kemski and Jim Showker). This task looks a LOT more daunting than it actually is. Getting to the underside of the AF Board is simply a matter of undoing the screws that hold the frame surrounding the

board itself to the chassis and unscrewing a ground lug connection to the chassis at the rear of the board. No unsoldering of wires connected to the board is necessary and you probably don't need to unplug anything (though I did to clean the headers, etc.). You can simply flip the frame and board assembly over and go to work with your desoldering tool or, in my case, 25 watt miniature iron and Soder-Wick. It took less than ten minutes to remove the old relay and install the replacement. The result was dramatic. Not only did my T/R problems disappear, the receiver audio actually sounded considerably better. Who knew?

* One other repair that I performed on my TS-830S was necessitated by a total lack of drive in the TUNE position. Our resident guru, Terry, suggested the problem might lie with R15 and/or R16 -- screen voltage dividers on the Rectifier Board. I tested them and, sure enough, R15 was open. I replaced both -- just 'cuz I was there -- and the TUNE function sprang to life. I am told that this problem is not altogether uncommon. Once again, access to the underside of the affected board was simple and the component replacement task quick and easy.

I will confess that I was shy initially about working on these radios myself. Sure, I have restored to as-new condition such densely packed beasts as the Hallicrafters SX-28 and SX-42 receivers, the Hammarlund SP-600 and the Collins R-388. For whatever reason, though, I thought the Kenwoods -- totally foreign to me (yuk-yuk) -- would be at least as intimidating. I was wrong. The TS-530S and TS-830S (and, I suspect, the 520 and 820) are a joy to work on. Their modular construction and excellent build quality make most service tasks, if not always dead simple, at least doable by the average guy who can harmlessly wield a screwdriver, needle nose pliers and soldering iron.

Best of all, once you're done fiddling you'll end up with a truly wonderful radio.

SINCERE THANKS TO JIM, KEN, TERRY AND ALL OTHERS WHO HAVE ENCOURAGED AND COACHED ME. I'll probably be back with more mysteries and queries before long, but I've learned a lot thus far, thanks to y'all.

VY 73,

Craig

Terry
That's the problem,as i can not load it up
Here is the step's i take.
First check ip for 60ma, ok
next,meter to ALC,,good peak
next meter to ip,in tune position,flip send and nothing on the
meter,nothing to dip
I then put the meter on RF and peak the plate and load,which will give
me about 50 watts out.
Note,the load control will flicker,when i try to peak the plate and load
in the RF position.

Maybe this would help me

Dear Craig

Thanks for taking the time to spell all that out. As someone just embarking on restoring an old 530, I found your experience quite inspirational. I feel much more confident about my own project now.

Best regards
Geoff VK2HQA

I must emphasize that every bit of the admittedly scant but useful knowledge I have on these hybrids came directly from our online friends here and from Jim and Ken's terrific websites (and links from them).

This is a great online community.

I know you'll enjoy your 530, from start to finish.

Don:

OK first of all no need to check the resting plate current every time you load up your rig. Set it to 60ma and should be good for quite some time. So for the near term dont worry about it.

Try loading in CW mode. Have to do this quickly.

After peaking the Drive in Tune mode then unkey the rig and place in CW mode and place meter selector switch in IP. Get hand on the Plate Capacitor then flip to send and see if you have plate current indication and quickly adjust the Plate capacitor for a dip. It may not dip at the white band reference mark on the arc behind the knob and that is OK for now. If you cannot get a dip anywhere in the travel unkey the rig.

If you get a dip then switch to RF meter position and tune the Plate and Load capacitors for maximum relative power on the meter. When done unkey rig. Switch the meter to IP and key rig again and make sure not exceeding 260ma.

Report back your findings.

Terry
Will print this out as usual and have a go at it later tonight.
I did check the voltages out on the tubes and all seemed close to spec's

Many Thanks
Don/Ve2ud

Ravi:

Lets regroup and make sure I understand the problem statement so not going off on a tangent.

I will take a shot at it:

In LSB, USB, and CW modes off air signals are very weak or non-existent, audio level in the speaker is low and there is no S-meter deflection. The Marker signal produces a low level audio tone in the speaker, but no S-meter deflection. The S-meter does deflect up scale when the RF gain pot is lowered from full open or CW position.

When injecting 8.0mv @ 8.830mhz test signal at the output of the receiver 1st mixer (TP-2) on the RF board there is audio tone from the speaker, but the audio level is not normal and there is no S-meter deflection.

Please correct or amplify on this so I can determine if we need to alter our approach.

Terry K9TW

OK that is good. While you are measuring things with rig down powered measure the cathode meter shunt resistors. Should not be much above 5 ohms.

Wait for awhile as it takes time for the 300 and 210 caps to discharge. Discharging the HV caps wont address voltage remaining on the final tube socket board.

Dieter:

I dont think anyone has had time to respond yet and I am a little overtaxed at moment.

So quickly it appears that you most likely had final tube arc over. When that occurs you momentarily apply 900vdc from the anode to the suppressor grid/cathode and only thing that limits that current is the cathode resistors and ESR of the transformer. For a moment you have 900vdc across those meter shunt resistors and that series meter multiplier and meter movement sees that high voltage instead of the approx 1.0vdc it would see at 200ma of plate current. Very lucky not to have lost the meter movement. Ordinarily this does not hurt the power transformer so may be some other operator abuse issues such as long key down times, loading in excess of max plate current, running high duty cycle modes without reducing plate current etc.

Did you do an internal visual of the PA cage? If not, then do so after discharging the HV filter caps. Pay special attention to the large rf plate choke to ensure not discolored and look at the small vhf rf choke and the rf bypass capacitor at base of the big choke. These will also discolor and the cap will even split open.

If all looks good there go ahead and do the coil pack and IFT alignment and can follow the procedure listed in the Operating manual under the Maintenance Section 6. Do the Receive and Transmit coil pack and IFT alignment.

Hi,

I have a TS-830S on the way and the seller says the serial number is in the "20 million" range. From everyone's experience, where does that place the rig in the total Kenwood production run?

Thanks and 73s,
Ken

Craig,
Thanks for those nuggets of wisdom - sage advice indeed! I appreciate all the info-sharing that takes place here. I'm sure I'll be asking my share of questions, as I have a (known) dead TS-830S on the way.
Regards and 73s,
Ken/WB4EJZ

Hi Terry, and thanks for the response.

Yes I figured it was likely an arc that caused plate voltage to end up where it shouldn't have been that was the likely culprit. For what it's worth the 6146Bs that were in the radio when I got it were Chinese and both of them have discolored plates and rattle when shaken...certainly abused.

Anyway, yes the plate choke is fine but the smaller choke from B+ to the bottom of the plate choke at the bypass cap was blown open. I replaced the choke, bypass cap, and blocking cap as well to be on the safe side. Additionally the cathode shunt resistors and screen resistors have been replaced as well since they were not originals and poorly done.

Transmit works perfectly and looks great on the waterfall of my SDR rigs. Good reports on the air too...it's just the drive control that's way out of whack from the receive side.

I'll run through the necessary alignment steps to try and get transmit and receive to match up and report back with how it goes.

Thanks!

Subject: [TS-520_820_530_830] Lessons learned

This is primarily aimed at newbies -- like me -- who have just joined the Kenwood hybrid community.

I am a convert. As proof of my new obsession, I have now purchased three hybrids - two TS-530Ss and a TS-830S. One of the 530s is in the expert hands of Jim Showker. The radio was essentially unused in mint cosmetic condition and still in its original, unmolested boxes when I obtained a month or so ago. And that was the problem. Decades of disuse rendered the radio pretty much inoperative due to tarnish and corrosion on connectors and contacts. Jim and his boys are bringing it back to life now.

Although I have no regrets whatsoever about sending my mint prize to Jim, I now realize that I may very well have been able to resurrect this radio myself (although, admittedly, I don't have the nifty lab gear -- sweep generator and such -- to do the very best post-service alignment possible.

I worked on the other two radios personally with the invaluable aid of friends on this reflector and have both Kenwoods working very nicely now. The quality of their construction makes repairing these wonderful radios a fairly painless task. Here are some lessons learned from my experience:

* Firstly, do NOT be offended by the oft-repeated advice to unplug your radio, let it sit idle for a spell and then discharge the HV components through the top of the plate choke in the finals cage before poking your fingers into or even near the machine's innards. Your friends are not assuming you're an idiot or careless when they pass along this counsel -- they're genuinely concerned about your welfare. It never hurts to be reminded. It does hurt to be bitten by 800 volts (though not necessarily for long).

* It has been recommended that the HV caps should be changed out as a matter of course upon receipt of your new/old hybrid (unless the previous owner has done so). Jim Showker and Ken Kemski both sell HV cap replacement kits that include the attendant resistors and caps. The job is easy and serves as a good introduction to the bowels of the radio.

* As has been mentioned time and time again, MOST problems from stock hybrids (unmodified or otherwise not messed with by previous owners) are due to tarnish and corrosion. The primary suspect is the band switch, the bane of nearly all older rigs, thanks to their vulnerability and mysteriously delicate construction. A gentle, thorough cleaning of all wafers, including those in the finals cage, cures many ills. DO THIS FIRST (unless your radio's working okay to begin with).

* The same goes for the circuit board plugs and headers (if you think these Kenwoods are bad about this, try working on a Drake TR-7). Unplug them gently, wipe the headers with a contact cleaner moistened Q-Tip and replace the plugs. Some of the plugs are in awkward places for hammy fingers to grab. I use a pair of needle nose pliers with plastic tubing slipped over the tips to extract these plugs. I haven't killed one yet.

* Relays are another vulnerable component. The antenna relay next to the finals on the underside of the radio (hidden by an easily removable metal shield) is subject to corroded or tarnished contacts. This can lead to "iffy" recovery in the transmit/receive cycle. The relay is a plug-in device (hooray!) and can be removed readily. The unsealed plastic cover can be snapped off (gently work the little tabs on either side of the base) and the contacts cleaned with a thin strip of paper moistened with contact cleaner. Don't be tempted to burnish the contacts with an abrasive of any kind - you'll do more harm than good). A replacement relay is available if yours is shot or damaged for some reason (possibly abused by a sandpaper wielding former owner).

* If cleaning the antenna relay doesn't clear up your T/R problems (like receiver noise and slow recovery or intermittent signal attenuation), you may need to replace the pretty much unserviceable RL1 on the AF Board. (Again, replacements are available from Ken Kemski and Jim Showker). This task looks a LOT more daunting than it actually is. Getting to the underside of the AF Board is simply a matter of undoing the screws that hold the frame surrounding the board itself to the chassis and unscrewing a ground lug connection to the chassis at the rear of the board. No unsoldering of wires connected to the board is necessary and you probably don't need to unplug anything (though I did to clean the headers, etc.). You can simply flip the frame and board assembly over and go to work with your desoldering tool or, in my case, 25 watt miniature iron and Soder-Wick. It took less than ten minutes to remove the old relay and install the replacement. The result was dramatic. Not only did my T/R problems disappear, the receiver audio actually sounded considerably better. Who knew?

* One other repair that I performed on my TS-830S was necessitated by a total lack of drive in the TUNE position. Our resident guru, Terry, suggested the problem might lie with R15 and/or R16 -- screen voltage dividers on the Rectifier Board. I tested them and, sure enough, R15 was open. I replaced both -- just 'cuz I was there -- and the TUNE function sprang to life. I am told that this problem is not altogether uncommon. Once again, access to the underside of the affected board was simple and the component replacement task quick and easy.

I will confess that I was shy initially about working on these radios myself. Sure, I have restored to as-new condition such densely packed beasts as the Hallicrafters SX-28 and SX-42 receivers, the Hammarlund SP-600 and the Collins R-388. For whatever reason, though, I thought the Kenwoods -- totally foreign to me (yuk-yuk) -- would be at least as intimidating. I was wrong. The TS-530S and TS-830S (and, I suspect, the 520 and 820) are a joy to work on. Their modular construction and excellent build quality make most service tasks, if not always dead simple, at least doable by the average guy who can harmlessly wield a screwdriver, needle nose pliers and soldering iron.

Best of all, once you're done fiddling you'll end up with a truly wonderful radio.

SINCERE THANKS TO JIM, KEN, TERRY AND ALL OTHERS WHO HAVE ENCOURAGED AND COACHED ME. I'll probably be back with more mysteries and queries before long, but I've learned a lot thus far, thanks to y'all.

VY 73,

Craig

Ravi:

Lets regroup and make sure I understand the problem statement so not going off on a tangent.

I will take a shot at it:

In LSB, USB, and CW modes off air signals are very weak or non-existent, (other than on 40 meters where signals are fairly ok) audio level in the speaker is low and there is no S-meter deflection. The Marker signal produces a low level audio tone in the speaker, but no S-meter deflection. The S-meter does deflect up scale when the RF gain pot is lowered from full open or CW position.

When injecting 8.0mv @ 8.830mhz test signal at the output of the receiver 1st mixer (TP-2) on the RF board there is audio tone from the speaker, but the audio level is not normal and there is no S-meter deflection. Same results when injecting 8.0mv@14.200mhz signal at TP-4 and at RB1 terminals. Voltages at RB1 terminal reads 1.03V in REC and minus 3.28V in SEND.

Please correct or amplify on this so I can determine if we need to alter our approach.

Terry K9TW

In LSB, USB, and CW modes off air signals are very weak or non-existent, (other than on 40 meters where signals are fairly ok) audio level in the speaker is low and there is no S-meter deflection. The Marker signal produces a low level audio tone in the speaker, but no S-meter deflection. The S-meter does deflect up scale when the RF gain pot is lowered from full open or CW position.

When injecting 8.0mv @ 8.830mhz test signal at the output of the receiver 1st mixer (TP-2) on the RF board there is audio tone from the speaker, but the audio level is not normal and there is no S-meter deflection.(Same results when injecting 8.0mv@14.200mhz signal at TP-4 and at RB1 terminals. Voltages at RB1 terminal reads 1.03V in REC and minus 3.28V in SEND)

Please correct or amplify on this so I can determine if we need to alter our approach.

Terry K9TW

OK typically a good coil pack alignment should result in the Drive control peaking at approx 1200 with VFO at around 200 in both receive and transmit. Sometimes you will find someone has cranked a ferrite core full in or full out. Be careful not to crack a core. Sometimes I apply just a drop of lube from a toothpick at top outer edge of core to get some lube to flow down between it and the cardboard former before I try to turn them. If you get a real stubborn one the tip of a soldering iron applied to the core will usually free it up. Sounds like you have done some good work and close to getting it where it needs to be.

I have never used the Chinese final but have heard nothing good about them. I try to use RCA 6146Bs when can get them but also have had good luck with JAN6146W (Sylvania).

When that occurs you momentarily apply 900vdc from the anode to the suppressor grid/cathode and only thing that limits that current is the cathode resistors and ESR of the transformer. For a moment you have 900vdc across those meter shunt resistors and that series meter multiplier and

meter movement sees that high voltage instead of the approx 1.0vdc it would see at 200ma of plate current. Very lucky not to have lost the meter movement. Ordinarily this does not hurt the power transformer so may be some other operator abuse issues such as long key down times, loading in excess of max plate current, running high duty cycle modes without reducing plate current etc.

Well shucks....I can't seem find my small blade alignment tool for the antenna and mixer cans but my larger one fits the drive cores just fine. Until I figure out where the heck that tool went I simply checked the antenna and mixer coils appear to be at least close since peak deflection of the S meter when dialed to the calibrator mid-band and drive is at 1200 when VFO. I touched up the drive coils to peak the ALC at the same DRIVE position and the radio is now working as it should. Some of the drive cores weren't even in the right ball-park.

Once I find the missing alignment tool I'll fire up the Boonton sig gen and scope so I can do a proper full alignment but as of now it looks like this abused radio is back in service.

By the way I had a spare set of NOS 1960s RCA 6146Bs still in the box along with a NOS 1960s RCA 12BY7A driver so it's now tricked out with some nice finals instead of some potentially troublesome Chinese parts.

Thanks for the advice Terry!

43203. TS-830-S Noise Blanker loss of effectiveness

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-03 02:18:00 UTC
From: kf4ofi
Topic: 43203 Message: 43203

First here is what I did... I pulled the IF board out and changed the 455 Murata filter with one from a 930. I didn't like it and changed it back. After putting it back together I notice that an electrical noise in my neighborhood was rather noisy. Tried increasing the noise blanker and no help. The noise blanker has always in the past been able to handle this noise with no problem, now it doesn't seem to do anything at all. Tried on several bands and other noises that it usually works great on and no help.

I have checked all the connections that I had contact with on the IF board and have found nothing.

Any ideas what I may have done or where I could look?

Thanks
Curt

Ravi:

If 40 meters is working and providing normal S-meter indication then can have no problem on RF board or IF board with exception of missing or low VCO signal at TP-3. VCO is the LO for the Mixer. Level is important.

Injecting substitute 8.830mhz RIF signal at TP-2 should have resulted in same action as you are seeing on 40 meters with exception you should have seen 30 over S9 with a 8mv signal.

Set your Sig gen to 7.200 and inject in to the SO-239 connector. Increase the RF output level until you get S9 indication. Assuming your S-meter is reasonably caled this is approx 50uv output level from your SG-402.

Now note the Sig gen level pot setting and dont move it. Go to a dead band and set Sig Gen to 8.830. Assuming levels are relatively constant then inject this signal at TP-2 and you should have approx S7 reading.

If 40 meters is working we are actually wasting our time with signal injection. It tells me you have missing or low VCO signal level at TP-3 for all the dead bands. This is very unusual. Go to TP-3 and measure the level on all the dead bands. You should have approx 1.0 rf volts. Measure with your Rf probe and DMM. I have seen cases where the VCO cable connector at PLL board or RF board was bad, but should affect all bands and not allow good 40 meter operation.

Step 9 of service manual tells you how to adjust the VCO.

Also does this mean that you have approx S9 Marker signal on 40 meters?

Thanks Terry. I will test the way you proposed and come back.

Meanwhile need a clarification, you said to measure RFG voltage at connection 6 on IF board.But according to schematic,RFG terminal is at Connection 8 Pin 2.
I assume you are referring to RIF terminal voltage at Connection 6 Pin 6.right?.

When you say filter switching diodes,are they D7 & D10 or D1 to D6 ?

Regards
Ravi-4s6rav

Subject: [TS-520_820_530_830] Re: TS-830S,need help

Ravi:

1. Injected 8.30Mhz/8milivolts signal to TP-2 - No s-meter indication either on fast or slow But audio was good (AF nwhile gain control at 9 o'clock position & RF control fully CW). When I rotate RF control to 12 o'clock position,s-meter goes up and stay & audio is low (which is normal I believe).

My Response:

Yes rotating RF GAIN pot from full CW to 1200 should produce upscale movement of the S-meter. Should have approx S8 TO S9 indication at 1200 position of RF gain pot.

No reason to test any further back from TP-2 on the RF board. Assuming Conn 5 and its solder connections are good then problem has to be on the IF board. Q1 and L41 have nothing to do with substitute 8mv RIF signal not producing S-meter indication.

Injecting 8mv @ 8.830mhz at TP-2 should produce approx 30 over S-9 S-meter indication.

Do the following:

1. Measure RFG voltage at Conn 6 on IF board. With RF gain pot at full CW position should read approx 3.6vdc.

2. CAUTION: Measure AGC voltage at Conn 15 Pin 3 brown wire. Do not rely on the brown wire. Make sure you are on Pin 3 and not Pin 1 where there is 300vdc present. Depending on input Z of your meter the AGC bus voltage will read low and drive the S-meter up scale. A 11meg VTVM will read approx 3.0vdc and S meter will read S4 to S5.

3. If above tests are all good then inject 8.830 at IF board as follows:

A. At IF board Conn 6 pin 6 inject 8mv @ 8.830mhz and see if S-meter comes alive. If it does, the problem is between Conn 6 on IF board and Conn 5 on RF board. If it does not,

then need to move down the IF chain injecting until you find where it is being lost. Problem is there are not many good test points in the path.

B. Go to IF01 on rear panel and inject same 8mv @ 8.830mhz. If comes alive then problem is with Q1 RIF amp. If it does not then move down to the filter switching diodes and inject there. Once you get past Q2/Q3 Mixer will have to change frequency to 455khz.

Lastly, are you certain you have an 8mv signal? Can you inject into a known good rig? Another hybrid would be good. 8mv @ 8.830mhz into the coax connector on rear panel will give approx S4 to S5 indication and using 14.2mhz @ 8mv will give approx 40 over S-9 indication.

Curt,

Give your NB switch and pot a blast of Deoxit (working pot through full range of movement) followed by good blast of canned air, may need to do more than once. If no joy then it may pay to do the NB alignment. You'll need DVM, SSG and noise generator. NB on with pot fully CCW, AGC set to fast, all work is undertaken on the AF board, . Inject SSG signal at at 20db in to rear panel so239, TP4 with adjustment to T1 and T2, adjusting to minimum. Remove SSG and connect noise generator to rear panel SO239, noise generator should be set to about s5-s9. Reduce the noise generator to below the threshold sensitivity and the turn NB control to Full CW, which should blank out the noise.

Before attempting to tune T1 or T2, it will pay to use a clean solder iron and heat the slug and then turn slug, this usually helps to prevent cracking the slugs

Subject: [TS-520_820_530_830] TS-830-S Noise Blanker loss of effectiveness

First here is what I did... I pulled the IF board out and changed the 455 Murata filter with one from a 930. I didn't like it and changed it back. After putting it back together I notice that an electrical noise in my neighborhood was rather noisy. Tried increasing the noise blanker and no help. The noise blanker has always in the past been able to handle this noise with no problem, now it doesn't seem to do anything at all. Tried on several bands and other noises that it usually works great on and no help.

I have checked all the connections that I had contact with on the IF board and have found nothing.

Any ideas what I may have done or where I could look?

Thanks
Curt

Sorry, I had typo it is Conn 8. No need to do any of that testing or signal injection at filter switching diodes if 40 meters is working. If you have good S-meter action on 40 it means that RFG is feeding the AGC bus with RF-1 3.6vdc voltage and that IF amps are working and AGC detector and AGC amp is working.

Ravi:

I am sorry I missed the detail about 40 meters S-meter. I have been trying to process a lot of information from a lot of sources. Clearly my own fault. I guess I am having a mental block.

Then I now understand that 40 meters receive operation is not NORMAL. It is very difficult for me to assess what is happening with 40 meters not being able to hear the received signals.

So I cannot tell if you have a receiver sensitivity problem or an S-meter indication problem or both.

Only way I could tell is to inject a known level into the SO-239 connector. 50uv or -73dBM will produce loud tone and S9.

What confuses me is you say you are injecting 8mv @8.830mhz at output of 1st mixer (a very high level RIF signal) and get weak tone in speaker and no S-meter indication. Yet at same time you tell me you can copy off air 40 meter signals and no other bands. Those two do not equate in my feeble mind unless you have some broadcast band 40 meter stations that are giving you 1.0 volt at the antenna? I could see this on 160 but not on 40. Are these ham signals or broadcast signals?

I think I would confirm that you have good VCO level on all bands at TP-3 and I would confirm have good LO at the 2nd mixer on IF board. This is measured at TP-1 on rear of IF board and is the VBT oscillator approx 8.375 @ 1.0 volts. This LO signal is required to produce the 455 IF output from Mixer Q2/Q3.

Again if 40 meters is working then Mixer 1 and Mixer 2 have to be working to some degree.

Sorry but I am lost at this point. You can continue your signal injecting efforts with some level to see if you find a point where you get good loud audio and good S-meter indication. If you go to output of Mixer 2 need to change from 8.830mhz to 455khz. You can work backward from the last IF amp Q8. If you inject 455khz at drain of Q8 the S-meter should work. If not no sense doing anymore injection until that problem is resolved. Not common to lose the detector diodes.

I know there are lots of ways to work on these rigs with modest test gear, but I am spoiled by being able to inject and measure known signal levels and recognize normal responses.

Perhaps someone else can offer something that I am missing.

>
> Set your Sig gen to 7.200 and inject in to the SO-239 connector. Increase the RF output level until you get S9 indication. Assuming your S-meter is reasonably caled this is approx 50uv output level from your SG-402.
>
> Now note the Sig gen level pot setting and dont move it. Go to a dead band and set Sig Gen to 8.830. Assuming levels are relatively constant then inject this signal at TP-2 and you should have approx S7 reading.
>
> If 40 meters is working we are actually wasting our time with signal injection. It tells me you have missing or low VCO signal level at TP-3 for all the dead bands. This is very unusual. Go to TP-3 and measure the level on all the dead bands. You should have approx 1.0 rf volts. Measure with your Rf probe and DMM. I have seen cases where the VCO cable connector at PLL board or RF board was bad, but should affect all bands and not allow good 40 meter operation.

Ken:

A 2 million series TS-830 is not a late model run. It is nice to know the production date run but no need to be obsessive over it. Lots of confusion about this topic. You can try to determine a date by looking at the date codes on the Counter Display board ICs.

Here are some dates I have seen;
1 million = 1981
2 million = 1982
3 Million = 1983
4 million = 1985
6 million = 1986 (have also seen 1990 claim which I believe is wrong?)
7 million = 1986

You will see far more 2 million series offered on eBay. I see far more 2 million series across the bench than others as well. No way I know of to tell how many were manufactured.

Also no way to tell if your 2 million has had later boards installed or different VFO installed with the change in hands over all these years. Just get it in good state of tune and have fun with it.

Hi Ken,

Yes it is a later model, there is a webpage that will give you an idea on year of manufacture in relation to the serial number, not sure name of site, perhaps another forum user may know.

If you do not have a pulse generator or a diode noise bridge or dont feel like making one there is another easy trick.

Get a universal motor appliance. The older the better. I have a $5.00 garage sale blender that has a ring of fire around its commutator when running. Perfect impulse noise generator. Set it across the room and turn on and it replicates power line insulator noise and will peg your S-meter and you can align the NB to completely null it out as indicated by the S-meter at S1 or less.

Yes the noise isnt fun but it is only for short time and you are looking at S-meter and not listening for the null.

If you get a blender just dont be tempted to "gin" up any mixed drinks while using it to align the rig!

> Give your NB switch and pot a blast of Deoxit (working pot through full range of movement) followed by good blast of canned air, may need to do more than once. If no joy then it may pay to do the NB alignment. You'll need DVM, SSG and noise generator. NB on with pot fully CCW, AGC set to fast, all work is undertaken on the AF board, . Inject SSG signal at at 20db in to rear panel so239, TP4 with adjustment to T1 and T2, adjusting to minimum. Remove SSG and connect noise generator to rear panel SO239, noise generator should be set to about s5-s9. Reduce the noise generator to below the threshold sensitivity and the turn NB control to Full CW, which should blank out the noise.

Couldn't have said it better myself, Craig. I've had my 820 a month and have learned a LOT just reading these messages and following the advice of the very helpful guys here. Obviously there is still a lot that is way over my head, but hopefully some of the local guys that offer to help me will be able to team up and get the 820 going.

When my friend was helping me Monday morning on the 820, he took the cover off the high voltage area tubes and showed the way he gets the voltage out of them. He took a screwdriver and touched it to the chassis and then touched the wires that were coming off the top of the 2 tubes with it.

Is that a safe way to discharge the high voltage? Just curious in case I open it up again. I don't want to shock the hound out of myself if there's a better way to do it.

43218. TS-830S Serial numbers in the grand scheme of things

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-03 13:54:23 UTC

Topic: 43195 Message: 43218

My newly revived TS-830S is serial # 1030342 and, according to a notation from the original owner on the back of the owner's manual, was purchased on Jan. 12, 1981 (from EGE, Inc.). So, this early one must have been manufactured in 1980.

Subject: [TS-520_820_530_830] Re: TS-830S,need help

Ravi:

I am sorry I missed the detail about 40 meters S-meter. I have been trying to process a lot of information from a lot of sources. Clearly my own fault. I guess I am having a mental block.

Then I now understand that 40 meters receive operation is not NORMAL. It is very difficult for me to assess what is happening with 40 meters not being able to hear the received signals.

So I cannot tell if you have a receiver sensitivity problem or an S-meter indication problem or both.

Only way I could tell is to inject a known level into the SO-239 connector. 50uv or -73dBM will produce loud tone and S9.

What confuses me is you say you are injecting 8mv @8.830mhz at output of 1st mixer (a very high level RIF signal) and get weak tone in speaker and no S-meter indication. Yet at same time you tell me you can copy off air 40 meter signals and no other bands. Those two do not equate in my feeble mind unless you have some broadcast band 40 meter stations that are giving you 1.0 volt at the antenna? I could see this on 160 but not on 40. Are these ham signals or broadcast signals?

I think I would confirm that you have good VCO level on all bands at TP-3 and I would confirm have good LO at the 2nd mixer on IF board. This is measured at TP-1 on rear of IF board and is the VBT oscillator approx 8.375 @ 1.0 volts. This LO signal is required to produce the 455 IF output from Mixer Q2/Q3.

Again if 40 meters is working then Mixer 1 and Mixer 2 have to be working to some degree.

Sorry but I am lost at this point. You can continue your signal injecting efforts with some level to see if you find a point where you get good loud audio and good S-meter indication. If you go to output of Mixer 2 need to change from 8.830mhz to 455khz. You can work backward from the last IF amp Q8. If you inject 455khz at drain of Q8 the S-meter should work. If not no sense doing anymore injection until that problem is resolved. Not common to

lose the detector diodes.

I know there are lots of ways to work on these rigs with modest test gear, but I am spoiled by being able to inject and measure known signal levels and recognize normal responses.

Perhaps someone else can offer something that I am missing.

>
> Injecting substitute 8.830mhz RIF signal at TP-2 should have resulted in same action as you are seeing on 40 meters with exception you should have seen 30 over S9 with a 8mv signal.
>
> Set your Sig gen to 7.200 and inject in to the SO-239 connector. Increase the RF output level until you get S9 indication. Assuming your S-meter is reasonably caled this is approx 50uv output level from your SG-402.
>
> Now note the Sig gen level pot setting and dont move it. Go to a dead band and set Sig Gen to 8.830. Assuming levels are relatively constant then inject this signal at TP-2 and you should have approx S7 reading.
>
> If 40 meters is working we are actually wasting our time with signal injection. It tells me you have missing or low VCO signal level at TP-3 for all the dead bands. This is very unusual. Go to TP-3 and measure the level on all the dead bands. You should have approx 1.0 rf volts. Measure with your Rf probe and DMM. I have seen cases where the VCO cable

connector at PLL board or RF board was bad, but should affect all bands and not allow good 40 meter operation.

Thanks Dave and Terry for your responses. As you intuitively suspected, I do not have the necessary equipment to "properly" align the NB, but the noises in my neighborhood should prove to be enough to attempt to adjustments. Now that I know where the NB is located I can diddle a little bit and see it there is something loose or not working properly. I had cleaned all the front panel switches and pots a couple of months ago, but I will go through them again.

Possibly it was just coincidence that this happened when I had the IF board out, but I feel I have done something to it. Should have just left it alone. Oh well.

Any other thoughts are still welcome.

Thanks
Curt

43222. TS-820 PLL

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-03 17:08:18 UTC
From: coyoteinventor@ymail.com
Topic: 43222 Message: 43222

I have a general question. Will replacing all caps on my TS-820 improve the reliability of the PLL (or at least the caps ones on that board)? Or not really?

My PLL locks when it wants to, and then it unlocks and goes crazy for a while. Switching bands usually helps. Other times it works great for a long time. I had a fellow ham radio tune it a couple of weeks ago and it worked well for a little while, but it's unlocking sometimes again and jumping around.

Thanks.

I seem to remember reading about a method of generating pulse type noise for testing noise blankers that involved scraping a wire across a metal file. Unfortunately I don't remember much more than that.
I don't remember if the file and wire were under power or grounded or what. It seems like there would have to be some kind of power to generate noise that you could hear.

I think it may have been on one of the Drake groups (I have followed those guys for years). A Google search should turn it up.

You can't get a cheaper noise generator than that.

A push mower will do the same thing. All you have to have is a pulse noise that acts like an ignition system on a lawn mower or your car.

I think you are referring to a low voltage battery with the negative lead connected to the file and the positive lead connected to one lead of a 100 ohm resistor and the other resistor lead scrapped across the file. This will produce sparks which will result in noise very similar to power line noise.

Terry's appliance idea is much better, you don't have to hold anything just turn it on and make adjustments to the NB.

You may have a bad connection or broken/cracked foil run that was created when you removed the board. I would check those first before you do anything else.

Topic: 43222 Message: 43225

The answer to your question about replacing the caps to fix a PLL problem is no. This is a common misunderstanding that caps are the source of most problems which is not true. There are problems associated with capacitors but those are few.

Your problem appears to be, based on your statements, dirty contacts in the VFO variable capacitor shaft to frame connection and the band switch wafers. If the VFO signal is disrupted, lost, for any reason, can result in the PLL going into UNLOCK. I recommend you clean the VFO shaft to frame connection with contact cleaner. Your problem can also be caused by dirty internal contacts in the PLL module (there are 2 boards inside the PLL module that interconnect with internal fixed pins). If these pins get dirty/corroded then instability in the PLL system can result in intermittent LOCK/UNLOCK states occurring.

Also try loosening the PC board mounting screws 1 full turn then tighten. Over time the screws become lose and dirt/corrosion occurs between the board and the ground which can cause problems. So clean the 820 then test. Be careful when removing the individual plugs on the modules. Use straight up pulling with very little rocking to remove the plug. Do NOT pull the plug wires to remove the plug. A pair of needle nose pliers will work, grasp the plug in the middle and pull straight up.

If you don't have the 820 service manual then download, you can't work on the 820 without it. There are screws that hold the module to the chassis, they must be removed after the plugs have been removed. Make note of how and where the plugs are plugged into the boards. If necessary, take a picture with your cell phone or digital camera BEFORE you remove anything! Don't assume you will remember how and where the plugs go, you can assume wrong!!

I dont agree. My rigs are not welding machines.

Depending on how soon after down power that you short the plate choke to PA cage with a screw driver you can get a large pop and transfer of metal. Impressive but needless. I dont want any pitting or burn marks in my PA cage.

Also, it is needlessly hard on the Filter caps to place a short across them.

I suppose if you always wait a sufficient time for the bleeders to do their job a screwdriver is fine.

I use a dual alligator clip jumper lead made from good flexible Belden 5kv test prod wire with good Mueller rubber boots on each clip and inserted a 10k 5 watt resistor in series in the middle. I heat shrinked resistor in place. Resistor is not critical just not too low and not too high. 10 ohms would be too low and 100k would be too high.

To use this safety tool I ring it with ohm meter each time to make sure it has good continuity. I connect one alligator clip to chassis ground and connect the other end to top of plate choke or at the HV filter caps. I dont tap it on I connect it and leave it in place to insure all stored energy is discharged.

If I apply it with 800 vdc on the caps then 800/10k = 80 ma of discharge current instead of potentially 100s of amps using a screw driver.

Just my opinion and how I treat my rigs and customers rigs.

A germanium diode in series with battery and a pot(to control the level)
makes a nice simple noise generator. Older ARRL handbooks had the
details. I built one back in the "good old days" and still use it today.

What I do is to turn on my variable heat
soldering pencil. It has an SCR that control the
heat from a pot on the base. Those are pretty
noisy devices. Anyway, if you stick a wire into
your SO-239 on the rear of the radio and lay it
near the soldering gun, you will have a good noise source for testing.

You can use a diode noise generator, but it is not as effective as an impulse generator.

The noise blanker works best on repetitive short duration impulse type noise ie auto ignition, power line insulator leakage, electrical contact arcing, door bell buzzer, electric fence etc.

I have a nice Palomar noise bridge and an Omega bridge and they just dont provide a repetitive ignition type pulse. The noise they produce is more like white noise. I use them with Spectrogram to align LSB/USB Carrier Osc. Great for that.

As I mentioned the hybrid noise blanker is most effective on repetitive impulse noise and wont work on random lightning or white noise or background hiss type noise.

I use to use my Palomar noise bridge to align Kenwood hybrid noise blankers and was not satisfied that I had them aligned as well as could be until I remembered the havoc my mom use to make on my receivers back in my Novice days when she would run the sweeper and blank out any and all reception. Even the diode ANL function in those old boatanchor receivers didnt help. Then it occurred to me I needed something with a commutator and brushes and the more dirty and worn the better to simulate what the Hybrid blankers are designed to act on.

Of course you can build an impulse noise generator by using a device that can be abruptly and fast switched like a Triac in a lite dimmer. You will get a fast (a few tens of microseconds)repetitive pulse rich in harmonics.

There are several simple impulse generator circuits on line that use SCR or Triac and 555 timer to trigger them.

I was suggesting a simple and cheap alternative to building a impulse generator. Maybe I will get around to building one with variable time constants someday and can retire the old blender.

Mark:

That makes sense to me and had not thought about the SCR control. I will have to check out my solder station. Maybe the old blender will go on the junk heap!

The blender will give me S9 plus about 8 feet away and I can almost completely null it. Will have to see what bringing short antenna near solder station will do. Sure would be a lot quieter!

Thanks for the suggestion.
Terry

I can upgrade your blender a bit.

"Sunbeam Electric Mixer" ca. 1967. That thing was the NOISIEST gadget going. It would shut down television and radio reception for a LONG way around, a couple of houses away, anyway, every time my mother would fire it up to whip some mashed potatoes or stir up a cake. It was the small, hand-mixer type and I've seen them for fifty cents in thrift stores.

I'm going to grab one for JUST this reason next time I see one. Thanks for the great idea.

I can see it now hundreds of hybrid shacks with sweepers, blenders, hand mixers and electric hair clippers running while aligning the noise blankers. Just make sure other rigs are not on VOX.

I may take Marks idea and run to Home Depot today and buy a cheap light dimmer, get a air conditioner AC motor start/run capacitor, an old auto ignition spark coil and make me a impulse noise generator.

Forgot about this as helped my kids use this approach for power source for their Tesla coil projects. By selecting value of the cap can get a nice fat white spark. Now that is the kind of test impulse noise we need.

Just have to be careful and not get on the 40,000 volts! I love the smell of Ozone.

OK enough fun with this.

43235. restore from mod CB in TS-830M and replace of 1s1555 with 1n4148

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-04 07:30:43 UTC
From: vierugo
Topic: 43235 Message: 43235

Hello everyone

I purchased a TS-830M used, where, unfortunately, is the change was made for 11 mt CB.

the change is that with the diodes as shown in the files section.
in my case the result is :

position 29 mhz -> 27 Mhz,
29.5 Mhz -> 27.5 Mhz

and are interested D26, D44, D48

Unfortunately, the diodes have been cut (D26), extracted (D44) and welded on (D48) and D44 link to D44;

At this point I have extracted, cleaned the contacts and replaced the 3 diodes with 1N4148.

When i powered on the rtx, there is a new problem:
1.8 - frequency display off
3.5 - frequency on , but if i switch appers on/of...on....(there seems to be a bad contact)
7.0 - frequency display off
10.1 - frequency display OK
14.0 - frequency display off
18.0 - frequency display OK
21.0 - frequency display OK
24.8 - frequency display OK
28.0 - frequency display OK, OK +500 Khz
29.0 - frequency display OK, OK +500 Khz

Before you try to remove D26 as before and try to reconnect with D48 D44 to verify if the cause is 1n4148, has anyone who knows what other modules or jumpers could have been changed for the 11 mT

Thanks to all for attention

Ugo

No, wait, I haven't contributed my thought, yet. We could hook up a key
to the line voltage, and use them as spark transmitters ! BUZZZ Buz
BUZZZZ Buz - - BUZZZZ BUZZZZ Buz BUZZZZZ. Whoops, sorry, I guess
the FCC outlawed that type of rig years ago. NEVER MIND ! ! !

Ugo:

I think this mod was done on component side of the board by cutting and splicing diodes? You may need to remove board and replace all involved diodes and make sure have good solder connections. Could have been some damage done during application of soldering iron heat.

Also, I dont think a 1N4148 is a recommended sub for a 1S1555 diode? A NTE177 is a sub for a 1S1555.

The 1N4148 is a fast switcher that has reverse recovery of 4ns and junction capacitance of 4pf.

The 1S1555 is a small signal switching diode with very low junction capacitance around 1pf.

The NTE177 has reverse recovery time of approx 50ns and junction capacitance of 1.5pf.

Not sure why Kenwood would have speced a low pn-junction capacitance diode for this application. The idea behind a small signal switching diode is that it is used where a small ac signal rides on top a dc bias voltage.

I have had no experience subing a 1S1555 with a 1N4148. Probably not related to your problem but just wanted to point it out.

Suggest you recheck your solder work and make sure traces have not been cut that you overlooked. Again if you tried to restore from component side of board might be better to remove and inspect board and replace all involved diodes.

Hopefully someone else will have had hands on experience with reversing this mod.

Jim:

If you like reading radio history read Robert Shrader W6BNB (author of classic text Electronic Communications) QCWA biography where he discusses 2KW Spark gap transmitters and Regenerative detectors on board ships where he served during the 30s.

Jim:

I forgot to mention if you are ARRL member go to QST archive and look at Jan 2006 article that Shrader wrote on history of transmitters. He covers the evolution of spark gap transmitters and talks about arc converter blowing up covering the operator with black soot when operator keyed it after failing to purge out the hydrogen gas.

I for one am glad transmitters are no longer rotating machines!

Looks like two of the bidders got the big itch and are driving the price up. Shown are the 599D series which was the last of the series. I still have my original ones that I bought back in the 70's. If interested, I would drop the seller an e-mail and ask if it includes the transceive cable.

Hi Dale,

Thanks, I saw those and its actually what got me considering a twins station. I emailed the seller on ebay yesterday and asked about the transceiver cable and for some history on the radios. I did not receive any response from him. I always get somewhat concerned when a seller on ebay won't respond to questions. They do look like very nice units. Probably early production.

Thanks again,

Tom

hi Tom,
I suggest you to select D series that is a later version with improvement and black (Dark grey) face which looks better in my opinion.
You can find aroound $500 or less. $750 is way too high. I bought one set including cables about 5 years ago at the swap meet for $100 for all. hi hi
Best luck.

Subject: [TS-520_820_530_830] WTB, Kenwood twins

I have returned to ham radio after a very long (career long) absence and would like to set up my old shack. I would like to find a set of "minty" Kenwood twins with cables. If you

have a set that needs a new home please contact me.

Thanks so much

Tom

I would also agree on the "D" model. A bit more attractive golden front panel and the MIC gain is on the front panel as opposed to under the hood.
$400 or thereabouts is a good price.

Hi Dale,

Thanks, I saw those and its actually what got me considering a twins station. I emailed the seller on ebay yesterday and asked about the transceiver cable and for some history on the radios. I did not receive any response from him. I always get somewhat concerned when a seller on ebay won't respond to questions. They do look like very nice units. Probably early production.

Thanks again,

Tom

There is a clean set of the original 599's on eBay:
321153218367Item #

Pricey and the seller does not mention the transceive cable.

43246. Re: restore from mod CB in TS-830M & replace of 1s1555 with 1n4148 : RESOLVED

Hi Terry

Thank you for info:
is not simple but the nte177 may found in Italy ...

I found what is the problem :

During inspect with glass i found near D27 a kind of imprint:

initially I had seen it but I thought it was the resin that comes when you solder any part and that once removed leaves a footprint:
NO actually the problem was that there was a footprint but a track completely eliminated , burned , by those who had made the change for the CB
After confirmation had a tester, I redid the link at the bottom with a small wire as bridge and the result was:

the band switch passes in all bands from 1.8 to 29.5 in the
correct way and using (I did not yet available NTE177) the
1n4148 did not affect the proper operation of the counter

I hope that this result can also be used for others like me who have tried or are trying to remove the CB in ts-380S/M

Ciao
Ugo

OK very good find. Bright light and magnifier can be big help.

I have seen some 1S1555 available on eBay, but I would not worry about it unless you see some performance issue.

I just believe that Kenwood design engineers speced components for a reason and if possible best to go back with original if available. Not being an rf design engineer the reason is not always apparent to me. I guess the exception would be if there is a new device with better performance characteristics available today that was not available 35 plus years ago.

Glad you were able to restore this ham band transceiver to its original purpose. Have fun.

I assume you are referring to programming software for the commercial Kenwood 3312 hand held transceiver. The Kenwood 3312 "Instruction Manual" can be downloaded free at the following link:

http://cdn.shopify.com/s/files/1/0206/3552/files/TK-2312E_3312E_Instruction_Manual_B62-2262-00_English.pdf?1756

There is a Yahoo Group that appears to deal with Kenwood RSS software, see the following link:

http://finance.groups.yahoo.com/group/Kenwood_Rss/

There is also a website that appears to deal with the "KPG 134Dn" software, see the following link:

http://kpg-134dn.software.informer.com/questions/

Topic: 43251 Message: 43251

I am selling off some of my 830 stash of parts. First up is two Digital display/Counter boards Both work great one is part number J25-2771-23 and the other is J25-2771-13. They both will work in any TS-830S. I have tested them both.
Asking $40.00 each plus $5.50 shipping or $75.00 for both plus $5.50 shipping.
Next up is an internal VFO. Asking $45.00 plus $5.50 shipping. No Knob !
Contact me direct n6wk at n6wk dot com

Next is a very clean TS-830S front panel.
Asking $35.00 plus $10.00 shipping.

Pictures on request

Thanks and more to come in a day or so.
73,
Gordon

In fairness to the EBay seller, he contacted me and said he did have the transceive cables. He said he was selling the twins for his Dad. I would prefer the newer edition of the twins but if someone is seeking the first edition these would be nice.

The Twins that are listed are the late and last edition. They are NOT the first edition. If you mouse over the picture, you can see that the front panels are marked R-599D and T-599D. All the cartons for any of the editions only said T-599 and R-599.

Hi Terry&Group

Well here goes.
I took out the 6146a which i thought was bad and put in a 6146b that i had dropped on the floor[35 bucks down the drain] a while back and the glass had broken on it.
So i decided to put it in[not recommend]to see what would happen.
Well i got plate meter reading again and not quite half power output.The test tube[6146b] did not light up at all,so i decide to buy a new tube from a local tube seller.
Bingo,full output and ip plate current back to normal.
I did the carrier balance and now have good LSB output.I replaced the driver tube as it was week on ten meters.
I also measured the cathode shut resistors and they all checked out fine.
The only problem i had was that the load control was acting up when i loaded the rig in cw full output.It would jump back down or flicker on the rf meter.
At times i could load the rig with no problems and another time it would jump back down to zero reading on the rf scale and then jump right back up.
Right now it seems to have settled down.Some bands it would do it and other bands,higher in freq it was fine.
I will put it through its paces slowly to see if any other adjustments is needed as right now i am happy to see it alive again as i was sure it was heading as a parts radio only
Moral of the story,do not mix you tubes!

So many thanks Terry for your help as if it was not for you and others on this group.it would be back on Ebay as for parts only,not working.5 out of ten,sold as is no returns hi hi

I'LL be back

Hello everyone,
I love restoring the old hybrid rigs. If it is dirty and non working then I can't resist the temptation to buy it and restore it to like new condition. I ran across a non functional TS-530S a few weeks ago.
I have never seen a rig with such a thick coating of nicotine on it. It was the worst I have ever seen. I told myself there is no way I am buying this one. No way. Then I bought it. So I come toting this rig home. My wife immediately started complaining that my new purchase was stinking up the whole house. I agreed. So I pop the covers off to see what the inside looked like. It was disgusting. Thick sticky nicotine on everything. I took the knobs off and soaked them. I could not get all of the yellow off of them. I decided to take a few parts out and throw the rest in the local electronics recycle bin. I first made sure all of the HV caps were discharged. Then I took out the meter, VFO, Display, Front panel and tubes. I had read many a thread on using a dishwasher on antique radios. So I thought what do I have to lose. I put the knobs, faceplate, cabinet half's and RF cage cover in the dishwasher. I ran it on normal wash and air dry setting. They all came out looking like new. So what do I have to lose. I put the rest of the entire radio in there. I ran it with air dry setting and the radio came out looking like new. I took compressed air and blew out the pots and switches etc. and sprayed them with contact cleaner and lube. . Then I removed the boards and cleaned the printed circuit sides and the connectors. I cleaned the antenna relay and replaced RL1 and all of the HV caps. I also replaced the band switch coupler. I lubed all moving parts. I then cleaned and reinstalled the meter, Vfo etc. I left the covers off and let it sit for about three days. When I determined everything was totally dry I hooked up the antenna and ground and plugged it in and turned it on. It received great on all of the bands. I turned the heater switch on with the SG switch off for a while. Then I turned on the SG and checked the idle bias. I checked power out and had over 100 watts out except on the WARC bands. I had to cut the blue wire at AF board because the WARC bands were never enabled on the radio. I checked the alignment and all was ok.
I have made several contacts with the radio and it looks and works like brand new.
Now I am not suggesting that you go and pop your rig into the dishwasher. Please don't ! It could be very dangerous. Especially if the HV caps are not discharged ! I have a lot of experience working on old HV tube rigs. I did this out of curiosity and as a last resort. In my case the results were fantastic.

It just goes to show you though how good these fine old rigs are made !!!!

Oh yeah, My wife made me scrub the dishwasher out really really good !!! lol

Don:

Did you try cleaning your RF detector sensitivity pot on rear panel? If not try that first. Use Deoxit sparingly and run pot thru range several times and blow out with canned air. I like to try to get a little Fader lube in after cleaning. Many folks use external wattmeter and never use the internal RF sniffer and the pot sets in one spot for long time.

If you have an external SWR bridge see if its forward power position meter indication also flickers simultaneously with the rig RF meter. If it does then it is not dirty sensitivity pot or the meter selector switch contacts. It is actual change in RF output.

If external SWR indication flickers with the internal RF indication then try cleaning the rotor shaft wiper contact on the Plate Load capacitor.

Does it do this on all bands? Does it do it at same point of unmeshing the Plate Load capacitor plates? Hopefully this is not due to arcing over at that point. Can you hear any frying or arcing sounds at this point?

Terry
K9TW

Don:

I am sorry did not see your statement about the behavior on all the bands. Disregard my question.

I forgot to ask if you had original RL-1 Aux Relay on AF board and if you have ever removed and cleaned RL-1 Antenna TR relay.

Another very rare one is the solder connection at the SO-239 connector inside the PA cage. I once gently tugged on the tinned lead and it pulled right out of the connector.

If cleaning sensitivity pot and plate load cap doesnt cure this problem then two things to measure:
1. RF drive levels
2. DC voltages at 6146 tube socket pins

I would probably start with RF drive levels.

Both are easy to check. Come back if you need help.

Terry
Could you tell me how to do the rf drive level measurement
Getting ready to go for a few days of holidays,so will print out your
reply's and have a go at it next week
thanks

Don:

Have posted numerous times on this subject but may not be easy to retrieve. Takes a lot of typing to explain TX Level Diagrams and various test gear to take the readings.

Do you have a RF probe and VTVM?

Analog meter much better for watching RF drive level fluctuating.

If no RF probe/VTVM then an O-scope can be used.

Only need monitor RF drive levels at key points after you exhaust all the associated pot and contact cleaning I previously mentioned.

Can monitor the output of the TX Mixer at TP-4 on RF Board. Should have approx 2rms volts and steady under key down. If it is constant while RF output is varying you know that TIF signal from IF board is good and TX Mixer is good and problem has to be from output of Driver tube toward the finals. This is the RF drive level to the 12BY7A control grid.

To measure RF drive at output of 12BY7A at DRV you will need multi- diode RF probe or O-scope. Same with measuring the RF drive level at control grids Pin 5 of the 6146 finals. If you use your single diode probe you risk losing it. Not question about it if you use it at Plate of Driver Tube. Might get by at grids of finals but I wouldnt chance it.

Another thing you could do is run the Driver stage test and watch ALC indication. Do this with SG off in CW mode. Heaters on and key rig and peak Drive Control for max ALC indication (can set Car pot for ALC at top end of black box range). If ALC indication flickers it tells you that RF drive is varying.

Terry
I have noticed that the tubes are not as bright as my other rigs,and
also the ip plate reading is 250ma's
and when i back it down to 225ma the output power drops a lot.
My other rigs all read max 225 ma's.Maybe they are drawing too much current?
Something not quite right,but will have to put it on the back burner
until i get back
Thanks

What price range would a set of early Twins with connection cable and matching speaker be in? I have a pair I am thinking of selling.

I have a set in nice looking condition. The R-599 works great, I use it as an extra receiver in the shack, mostly on 40M. It has the transvetors for 6 and 2 meters is it. The T-599 has new belts
(o-rings?) on it this year, but I have not tested it anymore yet. This pair with the speaker and cable came from a SK donation to a local Ham Club a few years ago. I also have an extra MC-50 to my needs I could be talked out of the go with the Twins. (The TS-820s, TS-830s and TS-600 only need one each)

I planned to sort out the transmitter , but other time commitments keep getting in the way.

Don:

When you get around to it measure the filament voltage at the tube socket pins.

My two 830s both running 6146Ws begin to fall off if I try to load much above approx 225ma. I can reliably get 100 watts output into 50 ohm dummy load at 225ma. I have had some 830s that would load to 250ma and exceed 100 watts output. I dont remember any above that. 6146Bs generally will do a little better than 6146W, but certainly not enough to fuss about or make a difference on the receiving end.

When you say "back it down" to 225ma I assume you mean that you tune for max rf output at 225ma and not just reduce the IP reading?

Remember IP X HV = DC input power and if you can get close to approx 180 watts dc input power (800vdc X .225a)that is what the rigs were designed for. Of course Ip includes screen grid current so not a precise calculation. Also meter accuracy depends on the cathode meter shunt values and the series meter multiplier value. The metering circuit is not meant for precise measurement. I suspect about 5% is as good as it gets.

This is another reason I recommend folks buy a wattmeter. In addition to being a great loading aid it is handy diagnostic tool. If you can load into 50ohm dummy load and get close to 100 watts out you generally have a pretty good indication that your TS830 is working close to design TX efficiency.

Howver, loading to 800vdc @225ma does not guarantee you will realize RF output level that approximates 56% class AB1 efficiency (100 watts output). Normally it does, but not always. There can be reasons output power indicates more or less than what you would expect including problems in the PA and tank circuit and problems in the coax and the load. Problems with the RF plate choke, problems with Tank LC ratios, feedline open or shorts or combinations of XC and XL in the load can all result in different RF output level than expected.

Looking at the relative power in the RF meter position will tell you something is going on, but not very useful information.

Adding a wattmeter to your IP meter and HV meter is a good idea. Doesnt have to be a Bird. A Heath HW102 or a Drake W4 is a good choice.

Just my opinion.

Terry
To get full output,i get about 250ma reading,tuning the normal way.Nice
100 watts out.
I check the ip plate and find it is 250ma's.
I then back off the carrier to 225 ma's and then i get about 65 watts out.
What does concern's me,but maybe it shouldn't is that the tubes are not
bright orange compared to my other rigs.[Maybe half as bright]
Now when i did take out the bad 6146a and put in the broken 6146b the
good 6146b was very bright like it should be.
Yes if i want to fool with this stuff i should buy a good wattmeter and
a rf wattmeter as i am enjoying this part of the hobby a lot more.
Going to take all the info you gave me and read them when i am at my
daughter's country place.

Hope i explained it right,as it real hot here and humid,plus the Blue
Jays lost again,and i am packing as i go.
Bringing my QRP stuff to play with while i am on my short holiday.

43265. TS520 VOX board Q8 repeated failures

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-06 21:12:54 UTC
From: zl3ha
Topic: 43265 Message: 43265

Hi all
Has anyone experienced repeated failures of Q8 on the VOX board which then prevents TX activating? I have replaced it twice with a NTE290A, and D8 with a 1N4148 and the rig works ok for a while (maybe 100 or so transmit cycles, more or less)and then it fails again for reasons unknown. Any ideas will be much appreciated - thank you
73, Grant, ZL3HA

43266. Re: Early TS830's

OK Don enjoy your holiday.

OK when I reduce the Car Level from 100 watts @ 225ma to approx 200ma I get approx 80 watts output.

As I mentioned when you get time measure the filament voltage at pins 2 and 7 of each socket and from H terminal on the Final board to chassis ground. H will be approx 12.8vac and 2 to 7 should be close to half that.

Topic: 43265 Message: 43267

It is good that you are replacing the back emf or flyback diode at same time. It appears the 1N4148 is not protecting your transistor.

I wonder if you should try a 1N60 as opposed to the 1N4148. The germanium diode has lower turn on so will act faster and was the original diode speced by Kenwood.

You could try a MOV or back to back zeners or a Transorb, but should not have to modify the design. Also, trying the more modern devices could affect the relay drop out time (make it faster)?

I think I would go with a 1N60 and see what happens.

Thanks Terry
It's nice to get away and see some different scenery for a change.
Yes i did measure them,and i think they are fine.
Tube #1 pin#2 12.9volts ac
Tube #1 pin#7 6.4volts ac----------H is 12.9volts ac
Tube#2 pin#2 6.4voults ac
Tube#2 pin#7 nil
Plate 927/881
PIN#3 both tubes 254/223
Pin#5 both tubes 102/59 minus dc volts

I still think that when the 6146a shorted out it took something with
it,but it's working a lot better than it was.

Ok will play with it when i get back.

Take Care
Don/Ve2ud

Ok I cant think of many reasons other than low filament voltage that would make them glow less brite than your former tubes did unless different filament design like the RCA "dark" heater used in 6146 for mobile service (5 to 8 volt heater range)?

I suppose if the tube filament pins were oxidized could cause voltage drop a the socket interface. Maybe clean the tube pins and re-insert several times to wipe them?

Every band except 10M my TS520 ran 100 W output with 200 mA of plate current reading.

How are you "backing it down" from 250 mA? What is your plate voltage indicated on the meter under load (transmitting CW) ??
I would QUICKLY turn my loading capacitor counterclockwise if I dipped the Plate tuning to 250mA, and keep redipping the plate tuning and reducing the loading until I got 200 mA.
At that point I would obtain 100 Watts output on a calibrated meter.

Terry
I have noticed that the tubes are not as bright as my other rigs,and
also the ip plate reading is 250ma's
and when i back it down to 225ma the output power drops a lot.
My other rigs all read max 225 ma's.Maybe they are drawing too much current?
Something not quite right,but will have to put it on the back burner
until i get back
Thanks

Terry
I think i had a bad pl259 on the coax from my watt meter.not making a
good ground.
So far no arching,but will fire it up in the morning before i leave and
see if it does it from a cold start

"Drive" to the final grids is adjusted in the ALC position of the meter .
 Is that the Drive you are not getting. Not the same as output at all.
That should be peaked before you go on to tune the output network (Plate and loading controls)

Gordon-

There is a clear plastic pointer/indicator that sits behind the PLATE knob on the 830...would you consider parting it out by itself?

Subject: [TS-520_820_530_830] Selling 830 parts

I am selling off some of my 830 stash of parts. First up is two Digital display/Counter boards Both work great one is part number J25-2771-23 and the other is J25-2771-13. They both will work in any TS-830S. I have tested them both.
Asking $40.00 each plus $5.50 shipping or $75.00 for both plus $5.50 shipping.
Next up is an internal VFO. Asking $45.00 plus $5.50 shipping. No Knob !
Contact me direct n6wk at n6wk dot com

Next is a very clean TS-830S front panel.
Asking $35.00 plus $10.00 shipping.

Pictures on request

Thanks and more to come in a day or so.
73,
Gordon
N6WK

Ok here goes
I turned the carrier down fully counter clockwise and i get 100
ma's,think it should be 225
As i turn it up to 150 ma's i get no movement at all by adjusting the
drive control[alc]
Now here's the weird part.
By adjusting the carrier up in ma's as soon as i get output on the alc meter
and go back to normal tune up procedures it jumps right back up to close
260 ma's,every time
Every time i play with lowering the carrier ma's and retuning it,it
jumps right back to 260 ma's
I just tested it again and i need at least 220 ma's to load the drive
and output is only about 55 watts,
But hey it working good,just i don't think the tubes will like it a lot

John
Has been a long day and i am[maybe Terry too] getting ready to hit the sack
I am not great on the tech side,but i do know how to load the rig.My first rig was a ts520 over 37 years ago.
I got a ts520s over twenty five years go and still running strong and never touched.
I have two close to mint ts830's that i will only take the top cover off to have a peak inside
This rig i am working on was very close to being one of the first ones out and lots of problems with solder joints and who knows what else
I just brought it back from the dead[sitting on the shelve for a year] and with the groups help[mostly Terry] it is now working pretty decent except for a few adjustments maybe still needed.
It's a good one to practice trouble shooting on and it will help me down the road if my other ones fail.

Don:

Do I understand that while loading the rig if you turn the Carrier Level Pot full CCW with rig keyed you see 100ma on the IP meter???

Also why would you think it should be 225 ma? We can talk about that off the list if you like.

In Tune mode the meter should be in ALC position and Car Level Pot increased to get decent indication on meter to allow you to peak the Drive control. At this step NONE of the meter scales are being read or mean anything. It is just a relative indication to allow you to adjust the drive stage tune circuits to resonance. Use enough Car Level to give your self something on the meter to work with. Nothing less than far right hand end of the Black ALC box on meter face. What you are really looking at on the meter is the ALC bus voltage going down due to small amount of positive grid current flowing on the peak of the rf drive envelope being applied to the 6146 control grids. When the ALC bus voltage goes down it drives the meter up scale same as it does for AGC bus action in receive mode. After peaking this relative meter indication with Drive control then go to Ip and adjust the Plate Tuning capacitor to get your initial plate current dip.Now you are measuring final tube plate current on the Ip ma meter scale. Now it is safe to go to CW mode and load the rig. This initial step just makes sure your Tank capacitor is not so far off resonance that you have 300 plus ma plate current taxing the finals while rig is keyed.

If my question above is true then I suggest you check the Balanced Modulator carrier suppression. I would also measure CV terminal at Conn 8 on the IF board. With Car Pot full CCW you should have ZERO dc volts at CV. Not likely you have any voltage, but a quick check would be good.

The Balanced Modulator produces a 455khz double side band suppressed carrier output (DSBSC) which becomes your Transmit IF (TIF) signal and leaves the IF board and goes to RF board as input for your Transmit Mixer to produce the actual transmit frequency RF drive.

The only time you should have any output from the Balanced Modulator when loading the rig is when the Car Level pot is advanced off full CCW position. This supplies from approx 0 to 0.6vdc at the junction of D29/D32 to forward bias the ring diodes and unbalance the modulator and produce the 455khz dsbcc output. The other time is in SSB mode when you have Mic audio at input of the Balanced Modulator.

If you are seeing 100ma of Ip while trying to load the rig with Car Level pot at full CCW then you either have voltage from Car Level pot at its full CCW position or the Carrier Suppression has not been adjusted properly (can also have a failure in the BM but lets address carrier suppression first as it is the most likely cause).

Couple of ways to adjust Carrier Suppression. I have a PL-259 with two 100 ohm 1/2 watt resistors soldered from the center pin to the shell. Screw that on to the SO-239 and now have a 1 watt 50 ohm dummy load with resistor lead length that allows me to read the voltage across the resistors. Can use a RF probe/VTVM/DMM or O-scope, or RF millivolt meter

to monitor the voltage while I adjust VR-4 Trimmer pot and TC-3 Trimmer cap at Balanced Mod on the IF board. Adjust these trimmers for a minimum or null in voltage across the dummy load in CW mode. Then go to LSB and USB modes and go back and forth until you get the null balanced between them. This is touchy and wont be perfectly equal. Do this Carrier Suppression adjustments with the SG Switch off or your little dummy load wont like it.

Another way that works well is to use another receiver set near your TS-830 tuned to the frequency you will be nulling at. May need to place a short piece of wire in the receiver SO-239 and bring it near the TS830 so you can hear the Carrier. Now adjust VR-4 and TC-3 until you cant hear the Carrier in speaker or headphones. May not be able to get a complete null but should be able to get it very low.

With experience you will learn how VR-4 reacts vs how TC-3 reacts and the interaction between them.

After performing the Carrier Suppression go back and re-adjust the resting plate current for an Ip indication of 60ma in SSB mode.

With the Carrier knob at full CCW you should get 60ma of plate current .MAX !
Your reading is WAY off.
 Can you adjust the bias pot for 60 mA?
If not there is no negative voltage coming from the power supply.

Subject: Re: [TS-520_820_530_830] Re: Early TS830's

Ok here goes
I turned the carrier down fully counter clockwise and i get 100
ma's,think it should be 225
As i turn it up to 150 ma's i get no movement at all by adjusting the
drive control[alc]
Now here's the weird part.
By adjusting the carrier up in ma's as soon as i get output on the alc meter
and go back to normal tune up procedures it jumps right back up to close
260 ma's,every time
Every time i play with lowering the carrier ma's and retuning it,it
jumps right back to 260 ma's
I just tested it again and i need at least 220 ma's to load the drive
and output is only about 55 watts,
But hey it working good,just i don't think the tubes will like it a lot

Wrong! His problem is not due to NO -C supply voltage.

If he had no cutoff or operating bias at Pin 5 control grids of the 6146 finals the tubes would have glowed red and been destroyed a long time ago. I suggest you really need to start reading and following these threads from the beginning.

He originally could not set the resting plate current to 60ma and we helped him diagnose that problem by cleaning and cycling the bias voltage adjustment pot thru its range and measuring the bias voltage from it. It turned out he had one bad final tube.

He now most recently reports that his cutoff bias in RX mode is -102vdc and his operating bias in TX mode is -59vdc measured at Pin 5 with two good final tubes installed.

Joe, I could be wrong but if you are referring to the bias supply when you say

"...there is no negative voltage coming from the power supply."

then the IP meter would not display 100ma but rather the IP meter would peg full scale to the right and the fuse would blow (final tubes would be conducting to saturation levels). The 830's "negative supply" is the "-C supply" on the Rectifier Unit that provides all the negative voltage in the 830, including final tube bias voltage. The -C supply also provides the negative voltage that is applied to the final tube screens, through relay RL1 on the Rectifier unit, when the SG switch is set to "OFF".

The final tube bias voltage applied to the grids of the final tubes controls the flow of electrons in the final tubes. By varying the level of negative voltage, more or less negative, controls the flow of electrons in the tube.

The following example assumes there is no RF applied from the driver tube (CAR set fully CCW) to the final tubes. The example is only concerned about basic electron flow in the tubes, not RF amplification.

Lets assume that with -100VDC applied to the grids of the final tubes the tubes are "biased to cut off". The term "Biased to cut off" refers to a level of negative voltage that when applied to the grids of the tube results in no current flow in the tube, cathode current is "zero". This is what happens when the 830 is in standby (transmitter is not keyed).

Lets also assume that if we reduce the bias voltage so it's "less negative", say to a negative voltage level of -65VDC, the tubes will conduct resulting in an IP current level of 60ma. This is what happens when the transmitter is keyed.

Now, lets assume there is a complete loss of negative voltage from the power supply (again, the negative voltage supply is the "-C" supply on the Rectifier Unit). Since there is no negative voltage applied to the grids of the final tube to control the flow of electrons in the tube, every electron that is emitted from the final tube's hot cathode will race towards any positive potential they see, i.e., the screens and anode (plate) in this case, resulting in saturation levels of current flowing in the tubes, the IP meter will peg full scale to the right, and the fuse will blow, assuming the correct rated fuse is in the fuse holder.

43287. KENWOOD HYBRID USER NET (July 7th, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-07 19:11:04 UTC
From: mvgilger
Topic: 43287 Message: 43287

The Saturday's net on 40 meter had 12 stations checking in with poor band conditions. We had 7 new check-in's, KD8TJL, K2GAV, K2QU, WD8INW, KE8D, K4BOF, and KB1LV.

Out of all stations checking in, there was:

5 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
3 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 17 stations checking in under poor band conditions. We had 4 new check-in, KC9UVP, KV9O, KA9OYD, and K5SRG.

Out of those, there was:

2 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
6 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87

February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39
April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 30, Sunday's total = 27
July 2013, Saturday's net total = 21, Sunday's total = 17 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

73's,
Mark, WB0IQK

SO c- VOLTAGE IS STUCK SOMEWHERE BETWEEN CUTOFF AND NO BIAS BUT NOT -65v WHERE IT SHOULD BE
.
somewhere in the voltage divider resistors and adjustment pot is a changed value, look for a burned resistor. Bad pot ?

Subject: [TS-520_820_530_830] Re: Early TS830's

Wrong! His problem is not due to NO -C supply voltage.

If he had no cutoff or operating bias at Pin 5 control grids of the 6146 finals the tubes would have glowed red and been destroyed a long time ago. I suggest you really need to start reading and following these threads from the beginning.

He originally could not set the resting plate current to 60ma and we helped him diagnose that problem by cleaning and cycling the bias voltage adjustment pot thru its range and measuring the bias voltage from it. It turned out he had one bad final tube.

He now most recently reports that his cutoff bias in RX mode is -102vdc and his operating bias in TX mode is -59vdc measured at Pin 5 with two good final tubes installed.

And me, and probably some others out there, REALLY appreciate the lot of you who take the time to write these things.

Me, I pull out the schematics for my 520 (even when it's an 830 or something under discussion, since they MOSTLY have all of the same main circuits like the finals and the RIF/TIF and drivers and such, excepting the nicer add-ons in the later/newer rigs) and try to follow along. I learned tube theory in the sixties and seventies, and I -KNOW- I'm out of date.

Once I get the VTVM back to spec, and the old O-scope working again, and the really old signal gennie back in line, and so on... and can do more than just twiddle around with that 520, I'm going to need all the expertise I can manage to con out of you lot of insanely well-educated people, with your unparalleled generosity in sharing expertise.

Yeah, it might sound like a bit of flattery, but it's meant GENUINELY, and stems from the mouth-hanging-open, bug-eyed, "ye ghods I wish I knew this stuff HALF that well" feelings of total inadequacy I get when I read one of these Master's theses on hybrid radios.

KUDOS, the lot of yer.

I just told you the bias voltage pot has been cleaned and cycled and proven to be able to adjust the resting plate current.

If the problem is with the -C circuit why can he adjust the resting plate current in LSB/USB mode for 60ma Ip and then measure the bias voltage at Pin 5 at -60vdc? (Normal bias voltage will vary from rig to rig a few volts).

If his operating bias voltage is normal there is only one other way for the plate current to jump up to 100ma in CW mode with Car Level pot full CCW position when he flips to send to begin loading and that is to have carrier output from the Balanced Modulator (assuming there isnt shorted ring diodes which is very unlikely). Now how can you get carrier out of the BM if there is no dc voltage from the CAR pot? Maybe the following will help the lite bulb come on.

Do yourself a favor and remove the covers from your TS520 and do this:
1. Locate the Generator board, locate the Balanced Modulator, locate Balance Trim Pot VR-2.
2. Place rig in CW mode, set Car Level pot at full CCW
3. Place meter switch in Ip position
4. Flip to send and verify that the resting plate current is 60ma
5. Flip back to receive and insert your adjustment tool into VR-2 slot.
6. Keep hand on Send/Rec switch and Flip to Send and slowly adjust VR2 and when you see the IP meter jump upscale and you hear a groan, grunt, buzz from the PA cage and the Transformer quickly flip back to Rec. If your VR-2 is clean and smooth you will be able to set the IP to 100 ma or 150 ma or where ever you like. If it is touchy and dirty it may well peg the meter.
7. Set mode to SSB and Flip to send and adjust VR-2 for lowest IP level which should be close to the original 60ma resting current you had. Better to do full carrier suppression adjustment when you are done with this lesson.
8. If you still dont understand or believe what you just saw then connect your multimeter to Pin 5 of the finals and watch your operating bias voltage as you flip to send again and turn VR-2. It will not move from its normal -55vdc or so as your plate current runs up scale or pegs the meter.

Wes:

This is what I would hope most would do who are interested in learning how these radios work. It is why people like Mike and I dont just give and answer. We try to explain some of the how and why. It is also helpful to have others following along for a QC check and to keep me and others from straying off the path. If I am wrong will be first to admit it. Hate to bum dope anyone.

Part of problem is all advice is based on what we understand has been written and is being fed back. We cant observe the problem or any of the readings being taken. Sometimes can tell something is wrong if the readings dont make any sense or simply not possible.

My last gig from which I am now retired was as the lead technician, trainer, and all they left (after mismanagement by two morons gutted my department) of Tier Three computer tech support at a semi-major midwestern university (go, salukis? or don't, I never gave a single rip about "sports).

I spent ten or more hours a day answering stupid questions on the stupid telephone posed by stupid people about their stupid computers, machines they were too deity-condemned DUMB to even be allowed to own. (Ask me some day how I -really- feel about that job of more than a decade and a half...)

Or training others how to answer those questions. Using bum data provided by unobservant idiots who couldn't be bothered even to learn the correct terminology. (Imagine trying to help someone with a hybrid rig who used the terms "resistor," "capacitor," "coil," and "tube" interchangeably....)

I well understand your challenges. That's why I spend my time going over the replies you guys send, so that maybe SOME of that will rub off on me. (Takes study, there's no osmosis going on. You -earned- your chops with these rigs after a lot of work.)

Kudos.

Curt,
What happens when you try to tune RF? The first time I tried tuning my TS-830s the meter pegged when I tuned RF. I mentioned this to Ken (K4EAA) and he told me to turn down the RF meter control in the upper left hand corner on the rear of the radio. If you are not seeing any swing or too much swing, try adjusting the meter control. Try adjusting it for about 3/4 swing. It's just for reference at this tuning stage.
I'm a newbie here, just putting in my two cents.
Ralph (KB1ZYI)

Ralph:

I suspect you are correct that the RF detector sensitivity pot needs to be adjusted. One minor point you are not "TUNING RF".

When you use the RF position on the panel meter you are looking at a sample of the RF output power from your pi-network. They use a resistor voltage divider that is essentially connected to the center conductor of your coax connector and rectify the RF voltage with a diode and filter it and send it to your meter. It allows you to adjust the Plate Tune and Plate Load capacitors for maximum relative output power.

After you make your initial plate dip in Tune mode you can simply place your meter to RF position and alternately adjust Plate Load and Plate tune for a maximum on the meter. None of the scales are being used in the RF meter position. Once you get maximum indication unkey the rig and place meter in IP position and flip to Send again to make sure you are not exceeding maximum plate current for your radio. Typically 225ma for a TS-530/TS-830 and 200ma for all others.

At 100 watts out you have approx 71rf volts across a 50 ohm load. The RF position of your panel meter is measuring that voltage. So in theory when you get maximum indication in the RF position of the panel meter you are close to 100 watts output power into a 50 ohm dummy load.

When you get a few extra dollars invest in a wattmeter and you can leave your panel meter in the IP position and you can load rig to 100 watts out on the wattmeter and at same time see that you are not exceeding maximum plate current. No reason to do the old fashioned dip and load after doing the initial dip in Tune mode. The only reason you need to do it is in case the Plate tune capacitor is far from resonance for the band you are loading on and you would have very high initial off resonance plate current when you begin tuning which is needlessly hard on the final tubes.

The wattmeter in addition to being a good loading aid will also tell you at a glance when things are normal and when there is a problem. Much easier than interpreting relative RF meter indications.

> What happens when you try to tune RF? The first time I tried tuning my TS-830s the meter pegged when I tuned RF. I mentioned this to Ken (K4EAA) and he told me to turn down the RF meter control in the upper left hand corner on the rear of the radio. If you are not seeing any swing or too much swing, try adjusting the meter control. Try adjusting it for about 3/4 swing. It's just for reference at this tuning stage.

Argh. Sorry. Pet Peeve time.

I had one supposed 'radio expert' (He never got above Technician.) try to tell me that leaving a wattmeter in-line all the time was a bad idea, it cost too much power.

I found out why he was saying that when I was at his home QTH one time and got a look at his wattmeter (and most particularly his patch cables FOR the wattmeter).

People, for crying in the dark, INVEST a few cents more for the BEST, lowest insertion loss co-ax and the top-end PL-259 connectors that you can find, particularly when you're just making a TWO FOOT JUMPER CABLE!! I understand full well cutting expenses, but that is penny-wise and pound-foolish. The difference is going to be less than a buck or two. Even I can afford THAT, on my (Illinois, Nine-Land) STATE retirement!! I hope.... (Please, Gov, leave my pension ALONE!!)

This numbnug had some of that really junky unbraided shield (just a spiral of wire wrapped around the center conductor, rather than a full braided shield), skinny, high-loss, JUNK coax jumper with -259 plugs made out of pot-metal crimped on the ends, that he apparently got from some chicken-band section of a truck stop. Of COURSE putting his wattmeter in-line was costing him probably half of the ERP (at 2 meters).

Now, I'm all for eggs-on-horseback at a truck stop, but I DON'T buy radio parts there. Not even co-ax.

Make the best jumpers you can, clean the sockets and plugs before you insert and screw them down, and the losses are minimal.

I forgot to mention one other thing.

If cleaning and adjusting the RF detector sensitivity pot does not result in being able to obtain meter indication in the RF meter position then you may have lost Diode D9. I have had to replace a couple over the years.

It is a 1N60 germanium signal diode and is located inside the PA cage. If you find the diode bad check the voltage divider resistors R23/R24. R24 is mislabeled as 10 ohms and is a 10k ohm resistor. This gives you a 10/1 ratio so that 71 volts is reduced to approx 7 volts applied to the diode.

If you need to troubleshoot this circuit will need to make sure rig is unplugged and the HV filter capacitors are discharged before bare hand contacting anything inside the PA cage.

43300. Selling Yaesu FT-757GX, supply and tuner to focus on TS-820

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-09 13:23:02 UTC
From: Barry
Topic: 43300 Message: 43300

I'm going to sell my Yaesu FT-757GX Mark I, FP-757GX power supply, FT-757AT auto antenna tuner, MH-1 mic and original manuals and boxes so I can focus on using my TS-820. If you'd like more info, here's my webpage for info:

http://www.digcservices.com/ham/yaesu/Yaesu_FT-757GX_Mark_I_Set2.html

Now I'll clean up the 820 and see if I can get it transmitting!

OK Ralph no problem. If you stick with it long enough and have the aptitude and interest those fruits can be replaced by capacitors and inductors. Hopefully you will find them just as tasty!

No shame in not understanding how a pi-network tank circuit works. You are not in the minority. If you want to start building a library suggest you get a late 70s ARRL handbook and a copy of ARRL Understanding Amateur Radio. The latter is a condensed version of the Handbook. It will take you thru basic electronics and how receivers and transmitters work with very little math. A good primer for vacuum tubes is Basic Radio Course by John T. Frye.

To really understand this stuff need to understand what a capacitor and an inductor are and how they behave with AC applied and what happens when you place them in series and in parallel. Then can move on to understanding resonance and how a Tank circuit works and how a signal applied to the grid of a transmitting vacuum tube can convert the DC HV supply to a RF signal and how that signal can be coupled to a load ie dummy load or antenna. Understanding transmission lines and how a dipole radiates is left for your reading. A fellow named Maxwell did some work here and displacement current and coulomb field will keep you busy. Way over my head and just accept it on faith!

Essentially the 6146 transmitting tubes pulse the HV DC supply at the rate of the RF signal applied to the control grids. These current pulses at the anode are of not much use. The Tank circuit thru its "flywheel" effect converts those pulses into form that is useful and can be coupled to the antenna. The Pi-network is a form of tank circuit. It is usually analyzed as back to back L-networks.

Basically a Pi-network has three functions:
1. Provide a return path back to the power supply for the HV DC component
2. Transform the relatively low antenna load impedance (approx 50 ohms) to the relatively high 6146 tube plate impedance (approx 2000 ohms)
3. Provide a low impedance path to ground for the harmonic content of the plate current. Especially 2nd harmonic.

The ARRL Handbook will tell you how to select values for the two capacitors and the inductor and how to optimize efficiency with a discussion of L/C ratios and loaded Q.

I will let you read up on all of this assuming this teaser piqued your interest.

By the way I have been at it over 50 years and read everyday and still learn and re-learn all the time.

Have Fun

The transmit signal goes through BOTH filters, same as the receive signal.

Why are you considering applying an audio signal to the BM?

I left out something. Should have expanded my response.

The "AUDIO" itself doesn't go through either, the IF frequencies flow
through the IF filters. The speech amp audio is mixed with the CAR
signal in the BM and that "RF" signal is then processed through the IF
Unit filters and on to the RF unit. You can see this by studying the
830's IF Unit schematic.

Transmit signal path in transmit on the IF Unit.

The speech amplifier audio and CAR signal is applied to the BM where they both mix together. The output of the BM is fed to Q22 and the output of Q22 is fed to L25. The output of L25 is fed to CF2 then to Q23. The output of Q23 is fed to Q28. The output of Q28 is fed to L28 then to and through XF1. The output of XF1 is fed through D42 to to Q29. The output of Q29 is the 8Mhz "TIF" signal, IF Plug 6 pin 3, that is fed to the RF Unit where it is mixed with the PLL Unit's VCO signal producing the transmit signal that's fed to the driver and ultimately the final amplifier.

The transmit signal path is "similar" to the receive signal path. If you don't have the 830's high resolution "color" schematic, check Gordon's website and download it and study the signal paths for both transmit and receive through the IF unit.

If you're looking to apply external audio processing (ESSB type stuff) to the 830's balanced modulator, I wouldn't recommend it. Others have tried over the years, and it wasn't worth the time and effort.

Topic: 43294 Message: 43310

Hi Dave:

No not a typo. A little difficult to see and understand how a tube converts the dc anode voltage to rf power.

I wont take the space here to write all that. Just follow along on the TS-830 schematic.

If you were to look at the spectral content of the Anode current you would see the DC component Fo, the Fundamental component F1, the 2nd Harmonic component F2, and so on for the odd and even harmonic components.

Initially the Anode Blocking/Coupling capacitor C7 will be dc charged by the 6146 HV power supply to 900vdc across the plates. This capacitor is charged and discharged at the RF rate.

Without having a dc return path thru L3 and L4 Tank inductor and thru safety choke L5 to chassis ground VC-1 Tank air variable capacitor and VC-2 Plate load air variable capacitor will be charged to the HV power supply voltage level across the plates. This dc voltage can result in arc over between the capacitor plates and/or arc over at the band switch contacts.

L5 is often described as a safety choke to blow the fuse if C7 is leaky or shorted and keep the anode voltage off your SO-239 connector. This is true, but it along with the Tank coil is the DC return path to keep C7 DC charge and discharge voltage off the Pi-network air variable capacitors. Absent this return path you would essentially have a 900vdc "bias voltage" standing across the air variable capacitors. Few people think about the importance of this dc return path that the Pi-network provides.

With our Pi-network we are using what is called Shunt feed by feeding the plate voltage thru the RF plate chokes (main and VHF chokes). In old days Series feed was used and the Plate voltage was fed thru the Tank circuit so the dc return path to the HV power supply was directly thru the tank inductor. The tube, tank circuit, and HV power supply were all in series. With Shunt feed we dont have that situation, but the Tank components still see the dc charge and discharge of the DC blocking capacitor to anode potential which must be addressed.

Thanks for taking the time to read my response to the newer folks and for asking for clarification. I probably could have phrased it differently.

Bill,

The "calibration ring" which is right behind the main VFO knob should rotate when the main VFO knob is turned...just at a slower rate. The gear drive/reduction for the VFO dials are a marvel of engineering but, sometimes they get out of whack...especially if you just had it shipped. You should obtain a service manual. You will also need a small screwdriver set...regular and phillips to removed the various screws. Take pictures as you remove the main knob and the "calibration knob," and any other knobs/dials.
Take a close look at how the two inner dials operate. The outer most one has the "windows" in it, the inner one has grouping of numbers of 1,2,3, etc. There are many combinations..only one will be correct...it's really not difficult to get it right. There are two small set screws that hold the outer most dial in place on the shaft. Rotate the VFO shaft during disassembly to see if there is any binding...it's easier to feel withoutthe main tuning knob in place. I assume that the upper dial works ok.

I can assist you further...if given a more detailed description.

OH...by the way, the VFO does not have to be removed to do this!

Subject: [TS-520_820_530_830] TS 820S Calibration Dial (VFO)

I have a near mint TS 820. The VFO is stable and smooth. My problem is when rotating the VFO at some points the calibration ring will rotate also causing the inner dial to lose calibration. Any suggestions??

Thanks inadvance & 73

Thanks Terry for your suggestion.
I'll give it a go and report back after a trial period. Just awaiting arrival of the diodes and transistors in the next few days.

I have replaced it twice with a NTE290A, and D8 with a 1N4148 and the rig works ok for a while (maybe 100 or so transmit cycles, more or less)and then it fails again for reasons unknown. Any ideas will be much appreciated - thank you

Hi Terry,

I'm with you on L5.
My initial focus was limited to TS-820S manual VC1, L5/6 and VC2 pi.
I was seeing the plate RFC as the main DC return path but I do see the charging/discharging at RF rate.

Thanks for explaining

Dave:

You are correct with Shunt feed the 6146 tube dc current path is thru the plate RF choke so the tube, hv power supply, and choke are all in series.

L4 serves as the Blocking cap dc return path in your TS-820. Just drawn close to the RL-1 TR relay.

On reflection my statement about having standing 900vdc "bias" across the tank capacitor and loading capacitor absent L5 is not technically accurate. The Plate Loading capacitor VC-2 also has a low value load resistor shunted across it ie the dummy load or antenna so the dc voltage across it would be less.

So I should have said that absent Pi-network L5 to provide a dc return path for the blocking cap charge voltage there would be a standing DC voltage across the air variable caps and not tried to quantify it.

43318. Getting closer on the 820 but still not transmitting

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-10 14:51:57 UTC
From: Barry
Topic: 43318 Message: 43318

I took the 820 apart last night, cleaned and blew out with air everything I could get to in an hour and a half, and I actually got the digital readout to work perfectly well now. That is a HUGE plus.

I was hoping some of that cleaning and reseating of connectors might get it to transmit, but still no go. Trying to go through the tune process still pegs the meter backward past 0 - there's nothing going out, and even into the MFJ tuner dummy load, nothing is showing on the meter when trying to flip the SEND/RECEIVE button or on the mic.

If I flip the SEND/RECEIVE button quickly up and down in succession, the ALC meter does want to rise a little.

I had posted a picture last week of a wire that was in one of the connectors but wasn't sure where it was connected inside. It is connected in the third pin on the connector and spliced/soldered to a blue wire as shown in this picture:

http://www.digcservices.com/ham/TS-820-Wire-Splice.jpg

Not sure if that is normal or not, but I figured I'd follow up on last week's post.

As always, thanks to you guys for your patience and your input.

Barry,

From your picture and, looking at the RF board schematic...this is CONNECTOR RF-3, PIN-3. This is the HEATER
power feed to the driver tube. The connectors used are known to break and cause problems...maybe that's why it appears to be bypassed.
May I suggest that you get out the voltmeter and check to see if you have approx 12-13 VAC on the heater circuit. If not,
this may be your problem. You may also want to be aware the the two pins to the left of pin 3,Pins 1 & 2, carry 210 & 300 VOLTS
respectively.

If you are looking for a NO Test Equipment method here are a couple.

1. There is the old fashioned way of making small adjustments on the NC capacitor while trying to match plate current dip to maximum RF output. Even at reduced Car Level (30 to 50 watts output) it can be hard on final tubes and power supply as it takes many cycles to get it close. Also, this method is not precise as the maximum RF output does not always occur at minimum plate current. There is a technical reason why this occurs that takes too much typing here to fully address. Has to do with output rf voltage must be exactly 180 degrees out of phase with input drive signal voltage for true resonance. With Pi-Network tank circuits there is usually some phase angle difference. Also, we use RF feedback with these hybrids and want the feedback voltage to be at correct phase angle. What really happens is the plate current dip is occuring at tank circuit maximum impedance and not where the tank is purely resistive. I believe Yeasu describes it as their preferred method in the manual for the FT-101. In any event, I really do not recommend this method. I only mentioned it with this much detail in case you get a recommendation from an old timer to use it. Might work better with old Class C transmitters with link coupled tank and not a Class AB-1 Pi-network rig. Enough about that.

"Cold" neutralization with SG switch off is a better method.

2. Another method is to use another receiver tuned to same 10 meter frequency you are neutralizing at and set physically close with perhaps a short jumper wire for an antenna and adjust NC for a null on the S-meter and lowest audio from speaker. In this method you have SG switch off.

Make sure you use an insulated adjustment tool.

If you are going to own and maintain a Kenwood Hybrid suggest you invest in RF probe and VTVM for these kind of adjustments.

Along the line of Terry's suggestion on an RF probe. I have a nice Eico probe that works well. For absolute readings you would only have to change out a resistor in the probe- depending on the input Z of your VTVM.

$18 shipped USPS.

I forgot to mention you can get the LSB/USB Carrier Osc trimmer caps adjusted pretty close by using the Marker (25khz crystal calibrator) and the S-meter.

Richard Measures describes the method in the Maintenance section of the TS-830 Survival Guide. It works for all hybrids. Make sure you have the AGC set to Fast and rig on dummy load and light touch on the VFO knob as you approach zero beat.

Another easy method is to use Spectrogram audio spectrum analyzer software (older versions free on line) and a diode noise generator. Can use receiver background noise, but noise bridge is better. I placed a screen shot in the Files section. Very easy way to adjust and fun to see.

Just remember how it sounds in receive is how you will sound in transmit. Might want to listen to self using the Moni feature.

Probably the audio generator injection into mic line and rf wattmeter method is the best way to adjust, but absent that test gear the Marker/S-meter method works pretty well. Just listen to self on each sideband when done.

The transmit signal goes through BOTH filters, same as the receive signal.

Why are you considering applying an audio signal to the BM?

Barry,

Please also note that testing the finals in a tube tester will not guarantee that they will work correctly in the real RF environment(in the rig). The basic tube tester, tests for shorts,
"gassy" tubes and some other things...but will not test the RF functioning. I recommend, as other also, to keep a known good set of finals and a known good driver
tube around the shack. Good luck...keep us posted

Hey Terry,

    It looks to me(anyway) that one end of the" white wire" is tied into the "blue wire" that is normally feeding that connection and soldered on the other side of the board....the white wire looks pretty hefty...for this "repair"..but sometimes ya gotta use what ya got. I agree that L8 may have opened...or how about the nasty cracked/cold solder joints on the driver tube socket? I think that Barry may not be familiar with doing the checks himself...which is fine.
 I have seen 2 similar "repairs" but the the ones I've seen.. the blue wire was removed from the connector and soldered to L8 on the foil side. Worked, just not pretty...so... I had to return them back to factory specs/appearance :}

Hope you are feeling FB!

Hi Joe: Very good regards the caution. I wonder if choke L8 has burned open? I have never seen this "repair". Would be interesting to see where the other end of white wire goes.

Topic: 43329 Message: 43329

My early model TS-520 was hit by an AC power surge this evening during an unexpected pop-up thunderstorm. The fuse blew and I looked around for any visible after-effects and saw none. I put a slightly larger fuse in so I could give it a short burst of AC, and noticed the power XFMR smoked a bit during the brief hit of AC. During that time, it lit up and I had good audio through the speaker. Checking the diodes and caps, all look good on the ohmmeter, so I put the AC (and DC) meter on it and gave it short bursts of AC as I checked various XFMR outputs. The HV is fine on the AC and DC side, but the lower ACs are a good bit less than normal. When it's on for more than 3 seconds the XFMR heats up, so I'm very cautious with that. The DC outputs are also low, but with good caps and diodes (and speaker audio) I don't see any shorts that would be dragging down the power supply.

Is it possible the surge shorted some windings in the XFMR? Is that a common occurrence on this rig? Are there other usual suspects I should check out? I've done stuff such as removing the tubes, etc. I don't have a Variac and don't want to wipe it out if it's not already. If the XFMR is shot, does this become a Parts Radio?

This would make a fine RF probe for Kenwood hybrid work. Not likely to get a Heathkit 309C or PK-3 on Ebay for this price. Take out shipping cost and about the price of buying all the parts to make a nice professional looking probe (depends on what kind of junk box you have).

I would not worry too much about the scaling resistor as majority of the readings you will need to take will not require high accuracy.

If you have a FET Analog meter or DMM it is likely a 10meg Z meter so the scaling resistor required would be 0.414 X 10Meg = 4.14Meg ohm. Not a standard value resistor.

You can use couple of resistors in series if you want more precision. For your 10meg meters (this assumes they really are 10Meg) you could use 3.9meg and a 220k resistors in series. Available from Mouser..

I suspect the resistor in this Eico probe is a 4.7meg same as in the Heathkit probes and most home made probes to be used with 11Meg VTVMs.

Even this value of resistor is not technically correct. 0.414 x 11Meg = 4.55meg. Again a non-standard resistor value. Heath supplied a 4.7meg resistor in all their RF probes instead of 4.55meg as it is the closest standard value 5% resistor.

As a reminder the only place you cannot use Dales probe in your Kenwood hybrid is at the Plate of the Driver tube and at the Control grids of the 6146 tubes. Maximum RF voltage for single germanium diode probe will be approx 35v.

You may have to change out the end connector, but if you do not have an RF probe would not hesitate to buy based on being configured for a 11Meg VTVM. Of course you should know by now my feelings about why the VTVM should be on your bench along with your DMM.

Just wanted to make sure you didnt pass on this probe if you are concerned about it not being designed for your 10meg meter. A non-issue and/or an easy change.

I will take 10% Dale!

Dave,

You either have a shorted filter capacitor or a shorted secondary winding.

Which 'Low AC" voltages are you referring to?

1. 12.6VAC filament
2. 14VAC for the 14VDC supply
3.100VAC for the -C bias supply
4. 210 for the 210A/B supply
5. 300 for the 300A/B supply

Hi Curt. I have sucessfully applied ESSB audio thru the mic jack of my TS 530. I also swapped the stock 8.830 2.4 kc filter to an Inrad 2.8 kc filter. My -6db points are 100 hz -2.9 khz with outboard gear. I've found that the mic circuits in the hybrids are pretty wide without much work. There is a single cap change that will pass a few more highs. Do a search for that mod. Good luck.

Thank you for your advice Mike (W5RKL).

I am in the process of removing all the boards, one at a time, cleaning all connectors and contacts (sanding/filing a little and using deoxit), and tightening well all screws that connect the grounds to the chassis.

I was not clear on what you meant by cleaning the "VFO shaft to frame connection"; are you referring to the metal piece at the top that has 2 screws to hold it to the frame? I think that's the only piece that touches the frame.

I'm also going to open the VFO and clean it inside. I'm not sure how to clean between the fins though. Last time I just submerged that piece of the VFO in warm water several times. Also, looking at some instructions online, I was not clear what is meant by the "rear wiper" which I am supposed to use deoxit on.

I hope to be able to finish this cleaning process this weekend so I can test the radio again.

Thanks again for your help so far. I hope this yields good results! ;-)

Using a diode with low forward turn on voltage is more important than one with high amps capacity in this small control relay application.

You are dealing with counter emf and decay time. If you use a silicon diode instead of -300v you will see something on the order of -1.0v or greater. If you use a Germanium then approx -.40v and a Schottky -.25v. Switching times will be faster with the germanium signal diode and Schottky diodes. The time for dissipation can be in milliseconds. In all due respect, you can use a 100amp silicon power diode and it wont affect the back emf voltage level over a lower current diode. It is really about forward voltage and switching times.

The counter emf voltage level is a function of how long the relay coil de-energization takes. The faster the switch off occurs the higher the induced reverse voltage level will be. Maybe the substitute 2SA562Y transistor switches state faster? If going back to a 1N60 diode does not solve the repeated transistor failure I would be inclined to evaluate the transistor sub that is being used.

All snubber devices in shunt across the relay coil are intended to reduce the speed of the coil current decay time. Therefore they have to act quickly to switch state and provide an alternate path. A silicon power diode will act quickly but quick is a relative term.

Why is it that so many people think that the Kenwood design engineers just willy nilly picked components. There is a design basis behind specing components for every function and application. Yes engineers copy designs. No sense in re-inventing the wheel if someone else has done the calcs and proven it in the field. There is technical basis why they speced a 1N60 diode.

As I mentioned adding a series resistor to the diode, using zener diodes, movs, and transorbs are all snubber methods, but would require some trial to ensure drop out time is not adversely affected. A mod should not be required and that includes changing from a germanium flywheel diode to a silicon power rectifier.

How many TS-520 radios are in service daily that have not required changing the original flyback diode to a silicon power rectifier or any other snubber network? My guess is the vast majority.

In my opinion it is generally best to go back to original design as your first attempt to fix unless that design has proven to be flawed.

By the way 2SA562Y transistors can be had on Ebay.

It's more likely one or more of the diodes in the HV circuits shorted. You may have to unsolder one lead of the diodes one -by-one until you see a shorted one.

Subject: [TS-520_820_530_830] TS-520 Smoked

My early model TS-520 was hit by an AC power surge this evening during an unexpected pop-up thunderstorm. The fuse blew and I looked around for any visible after-effects and saw none. I put a slightly larger fuse in so I could give it a short burst of AC, and noticed the power XFMR smoked a bit during the brief hit of AC. During that time, it lit up and I had good audio through the speaker. Checking the diodes and caps, all look good on the ohmmeter, so I put the AC (and DC) meter on it and gave it short bursts of AC as I checked various XFMR outputs. The HV is fine on the AC and DC side, but the lower ACs are a good bit less than normal. When it's on for more than 3 seconds the XFMR heats up, so I'm very cautious with that. The DC outputs are also low, but with good caps and diodes (and speaker audio) I don't see any shorts that would be dragging down the power supply.

Is it possible the surge shorted some windings in the XFMR? Is that a common occurrence on this rig? Are there other usual suspects I should check out? I've done stuff such as removing the tubes, etc. I don't have a Variac and don't want to wipe it out if it's not already. If the XFMR is shot, does this become a Parts Radio?

73, Dave WA4FXT

I can see that. That is not the question. Where does the other end go? Is it tacked to L8, is it wrapped around the filament pin on the driver tube, is it tacked to the tube socket pin, etc.

Upon power on the Digital Display is correct. After 5 minutes the 2nd Digit (Mhz) goes to 9 and the remaining digits are correct, then 10 min later back to mormal. The receive functions correctly and is stable dispite the 2nd Digit.....i.e 7.250 reads 9.250.

Any idea's?

John, a shorted diode in the HV? I don't think so! Did you read the entire post especially where Don said he checked the HV AC and DC voltages and they appear to be fine? It appears you did not read all of the post.

Dave, you should NEVER, repeat "NEVER" replace an original "correct" rated blown fuse with one with a higher current rating!!! Why on earth would you do such a thing? Doing that harms the transformer more then if you replaced the fuse with the correct rated fuse!!! I just do not understand why people continue to do these ridiculously WRONG things when we have stated many times on the group to NEVER do that!!

As for the diodes "looking good", did you come to this conclusion by simply visually inspecting the diodes? If that's how you came to the conclusion the diodes are "okay" then you did it wrong! You cant tell whether a diode is good by simply visually inspecting it. You have to use an ohm meter to tell.

You said the "lower AC/s are a good bit less than normal". How did you come that conclusion? Did you disconnect the AC windings from the Rectifier Unit then measure the winding's AC voltage or did you measure the AC voltage with the circuit connected? If there's a shorted capacitor, the AC voltage WILL be low because all the AC voltage is dropping across the shorted capacitor but before that happens, more than likely any diode would have blown "open" resulting in loss of that supply's DC voltage. What AC voltage is lower than normal, 12.6VAC filament, 14VAC for the 14VDC supply, the 100 for the bias -C supply, the 210 and 300 AC voltages? Which one? We can't help you if you don't give the right voltages.

Can a power transformer fail due to a surge? Yes it can. If the transformer is shorted, regardless which winding is shorted, you can have it rewound using "Transformer Rewind Service"

http://members.tripod.com/tubes_tubes_tubes/transformerrewindingservice/id32.html

or find a parts 520 power transformer, there's one on eBay right now.

EXCUSE ME?? I *ALWAYS* replace the factory rated fuse with one that is at least 100% higher in value...Makes it *real* easy to find the defective part/circuit! LOL!!!

(Before anyone starts getting high and mighty here...that was meant to be humorous!)

BTW..I have a couple of 520's I may want to sell (With original factory manuals!)...1 is an "S", but I have never used it. The TS-520 has been on the air numerous times...forget what the output is...around 125, if memory serves..may be higher. The radio *does* need a good tweaking...hasn't been done for at least..OH...since it was new. I also have a VFO520..it drifts a bit until the temp stabilizes. (Hope whoever gets it, has a good pair of legs to keep up with it until it settles down! <<GRIN>> (Will not sell the VFO individually...it will go with one of the 520's) Absolutely will *not* ship..these puppies are just too heavy to play the shipping nightmare with..As you can see below...I am in Reno, Nevada. If you are interested, contact me OFF GROUP. Email address is in the header.

Joe - W7RKN
Reno, Nevada

Dave,

Now is a good time to suggest that you build a "dim bulb tester" or "transformer saver" before you go much further. Check the group's web site or google "dim bulb tester". The simple device will prevent blowing (the correct size) fuses and save your transformer (and other components).

Good luck with the repair.

Hi Terry
Hope all is well
Well back from holidays and i think my radio enjoyed the holiday too as it's working as it should in the load up procedure.
In Rf meter position i am now able to back the carrier from 250 ma's right down to zero now.
In IP position when i back it down,it goes to 60ma as it should
Maybe when i cleaned the pots i did not let them dry enough.
There is no more arching,as it might have been that PL259 you told me to clean.

I just have to do the carrier balance as LSB band works ok,but i have to turn the mic up higher compared to the USB.
Will go over the reply's you have me and and have a go at it when i get back to normal,what ever normal is
Thanks Again.

In the electrical power world I have used Hi-pot Burners and Thumpers (capacitor discharge) on HV underground cables and the Stator windings of large motors. Here you are intentionally causing damage as an aural and visual means of locating the fault.

In old days with 19.9kv URD in residential subdivisions pretty common for a line crew to close in on fault many times by re-fusing the cutout at the riser and repeated opening of the loop at pad mount transformers until faulted section of cable was isolated. Not a good practice especially if the fault is at the base of the pole where you are standing banging in 100amp fuses at 19.9kv. Today they have more modern TDR type test gear.

I have however never intentionally put a "penny" in the fuse panel to find a fault in any Hybrid! Sounds like Bob Mansker may have a customer.

Very easy to build a dim bulb tester. Even just go to hardware and buy a lamp socket with pig tails and a cheap extension cord and place lamp socket in one leg. Cant get easier than that. Can make as fancy as you want. My "good" one is on a pine board with On-Off switch and porcelain socket. I usually start with a 40 watt bulb, then 60 watt then 100 watt.

Not dissing or flaming or ranting or making fun of this member. Like Mike scratching my head. Just hope he can understand why it is not a good practice to up the size of the fuse and try again. Fuses do get tired and sometimes blow for no apparent reason.

Probably most of us who do not have dim bulb tester have re-fused and tried one more time after a good visual inspection, but if fuse blows again time to start troubleshooting.

Well Don you reported -60vdc operating bias on the 6146 control grids in TX mode. I specifically asked you about this. If your bias voltage pot was dirty, bad, or intermittent after cleaning no way to have proper bias voltage in TX mode. Unless you were just measuring it when it was there to spec and at that time you should have noticed that you did not have high IP.

You reported 100ma plus IP with Car Level Pot full CCW with rig keyed in CW mode. Only two ways for that to occur. 1. Did not have -60vdc on control grids or 2. Balanced Mod carrier was not nulled.

Assuming you have not adjusted the Bal Mod carrier null then at the moment you had this high level of IP you did not have the correct operating bias voltage on your finals.

I do not remember if you reported that Aux relay on Audio board has been replaced or not?

I guess it shall remain a mystery. Although your bias voltage was not "stuck" as JD proposed I will give Round 1 to him!

Bill,

If I may hazard a guess...you have a possible intermittent (thermal) problem with the counter/counter mix unit...that's the box
on the left side that is connected to the digital display(on top) with another multi-pin connector on the underside of the chassis.
There are numerous "posts" in the "files section" of this board, dealing with this unit. I would recommend that: with the power off..
AND rig unplugged...that you FIRST removed the multi-pin connector connector on the top...the one that goes to the display...clean with
your choice of cleaners...re-attach/detach connector several times...blow off with "canned air"....check for proper operation. If this does not
help, removal and a cleaning/inspection of the "DG-1 unit" board connector pins may be in order. Start with the simple part first...let us know your results

Subject: [TS-520_820_530_830] TS 820S Display Error

Upon power on the Digital Display is correct. After 5 minutes the 2nd Digit (Mhz) goes to 9 and the remaining digits are correct, then 10 min later back to mormal. The receive functions correctly and is stable dispite the 2nd Digit.....i.e 7.250 reads 9.250.

Any idea's?

Bill KB9IV

Well, I expected the firestorm and got it. I didn't put a penny (figuratively) in the fuse holder - only a slightly larger fuse. If it had blown, I'd stop right there. But yes, the incandescent lamp is something I've used in the past when a VariAC wasn't handy. I obviously didn't take the time to put one together for this test, but it does look like the problem is the XFMR. The middle group of AC voltages are the ones that were about 60% of normal readings, while the HV was fine and the 14VAC was fine. When I say the diodes and filter caps look fine, I'm not talking about a visual inspection (although I do that first): I checked them properly. I have now removed all the secondary connections to the XFMR and it still heats up after a few seconds. Sure seems like an internal short. (Unless there's something going on with the DC converter ..... heck, we used to use vibrators to convert DC to AC for mobile use -- what's with all this transistorized stuff?)

I'll either use this as an excuse/opportunity to buy a later model rig (with digital readout even!) and part this one out - or I'll go ahead and round up a replacement XFMR and carefully bring up the AC and check for any other problems.

Thanks for the comments and responses. I deserve the handslap for the unprofessional troubleshooting.

From: Mike
Topic: 43222 Message: 43350

Cesar,

No, when I say "variable capacitor shaft to frame connection", I am referring to the connection point at the rear of the variable capacitor shaft where the thin brass fork makes connection with the variable capacitor shaft and the capacitor's frame. This connection pointget dirty/corroded over time especially when the transceiver sits not being used, sitting idling on a shelf, for a long period of time. When this connection point gets dirty/corroded, that results in disruption in the shaft to frame connection, the VFO variable capacitor's capacitance value changes dramatically and rapidly when the VFO knob is rotated. This results ina significant change in the VFO's output frequency, even to the point the VFO no longer oscillates. This can cause instability in the digital display, such as the digital displays appears to be changing on its own, and also to complete loss of VFO signal, the VFO stops oscillating, which results in the PLL changing to an "Unlock" state, the digital display turns darkand loss of both receive and transmit.

If you remove the right sidepanelon the VFO enclosure, held to the enclosure by 2 phillips head screws, you will see the variable capacitor "shaft" with plates attached to the shaft. These are the "variable" or "movable plates"that "move intoand out of the fixed plates". When the variable platesmove into and out of the fixed platesthe capacitor's capacitance value changes resulting in the oscillator's tank circuit resonant frequency changing. That's how an "analog" VFO, variable capacitor and variable inductor, work. Drake uses fixed capacitance with a variable inductor while Kenwood used both variable inductance and variable capacitance. The variable inductor is adjusted during VFO alignment ONLY. The variable capacitor, attached to the front panel VFO knob, rotates when ever you change frequencies. This point on the VFO's variable capacitor shaft to frame connection should be cleanedwith contact cleanerand the VFO rotated throughout it's range several timesthen test for proper operation. If the problem still exist, maybe not at all points, then repeat the cleaning until the problem is not longer there. Follow all cleaning with contact cleaner with generous use of canned air or compressed air to remove any/all contact cleaner. Follow all cleaner warnings on the can. Some contact cleaners are flammable and it only takes a small spark to ignite the cleaner.

Y'all be sure and read my follow-up post in the original thread.
Have any of you ever said these words to a kid? "Do as I say, not as I do." I'm the first guy who'd say never do what I did as a test, but I know/knew the risks and was willing to take them in this particular situation. But I appreciate the reminder, and am open to accept the flaming. It's OK, and deserved.

Terry, I sure wish my local power utility would fix the problem on my line. The fuse blows every couple of weeks on one phase, and they come out and close it up and get 15 houses back in business. Of course, when they come out they always send a different crew who aren't familiar with the way the lines are run, so it takes some time to figure it out unless I'm home and run out to tell them where the fuse is located. Of course, no follow-up ever occurs, and the chronic problems keep the guys busy and employed.

Dave, from what you are saying, it does appear the transformer is shorted internally.

I believe there's a 520 power transformer up for sale on eBay. If not you can get the transformer rewound at the link I included in my last response.

Dave:

Crew should carry pole and phase maps on trucks and if a lateral with only 15 houses you walk it down to make sure no tree limbs on it or line is not down and then re-fuse and close in on it. Should not be a big deal. Big deal is calling out a crew if no longer have a servicer or troubleman on duty.

Unfortunately utilities have ended up doing like all other businesses. I spent almost 40 years with American Electric Power. I never thought I would see the day we would "down size" or "right size" but it happened and on black Friday many people were walked out the door. Some hung on and were offered "early out" packages. The knowledge and experience base that went out the door was astonishing. It was good for me as I came back under contract on my own terms until I had a heart attack and decided life was more important than money.

With Line Departments it is not uncommon now to rely heavily on contract help. Service area specific knowledge and experience is lacking and response time can be longer. Old time trouble men who knew the system like back of hand and took the service truck home and were dispatched from home are pretty much gone.

In house tree trimming has been eliminated and contract trimming budgets greatly reduced. Distribution system maintenance and upgrade budgets slashed. Probably years since fusing and co-ordination studies have been done. I dont know the age or physical state of your system. If it is 12kv it is probably quite old.

All I can suggest is you keep after them. If you are lucky you might get a trouble man who is a ham, but he is limited in what he can do. His hands are tied and he has to work within their work control system. Keep track of your outage frequency and duration and if storm related. Send a letter to your utility president and local manager informing them of the poor quality of service and make an appeal for action. Dont let them hide behind the system being at the mercy of the elements if outages are not storm related. I would say be persistent and if cant get response then maybe bring to attention of your local news organizations. Some communities have Action Lines for these kind of things.

I was once on the hot seat when ordinary citizen, taxpayer and customer (old fashioned notion) made a street light outage study and sent it to utility president. The city was paying the light bill and not getting what they paid for and public safety was being jeopardized. Local news picked up on it and street light repair became a very high priority.

OK back to Hybrids.

>
> Terry, I sure wish my local power utility would fix the problem on my line. The fuse

blows every couple of weeks on one phase, and they come out and close it up and get 15 houses back in business. Of course, when they come out they always send a different crew who aren't familiar with the way the lines are run, so it takes some time to figure it out unless I'm home and run out to tell them where the fuse is located. Of course, no follow-up ever occurs, and the chronic problems keep the guys busy and employed.

43363. TS 820 Display Error

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-13 18:43:16 UTC
From: Wm Marvin
Topic: 43363 Message: 43363

I have had no luck correcting the display error (9)for the MHZ digit.....i.e 9.150 for 7.150. My 820 front panel looks brand new because someone has reworked everything on and behind the panel.

The Service manual does not show the Counter Unit views but the PLL board is shown. I suspect either the Counter Unit or PLL,maybe, as the receive function is not affected by this display error.

Last night I treated every edge connector and plug-in connector their is and all circuit board mounting screw(s) and was surprized at the overall receive performance increase.....WoW.

I corrected the VFO sticking calibration ring and now the the VFO rotates with little effort using the KB-1 know that was supplied.

Any ideas for the Mhz digit error would be welcome.

Best DX....Bill KB9IV

Have you soldered all of the feed through holes
on the two PCB's inside of the counter unit? Service Bulletin #26 covers this.

43366. Nicely refurbished TS-530S for sale

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-13 19:54:56 UTC
From: Craig Roberts
Topic: 43363 Message: 43366

Hi y'all,

I have finished my TS-530S refurb project and am ready to part with it (I have another 530 and an 830 as "keepers").

Besides now looking near new, this beautiful radio has:

* Kenwood 500 Hz CW filter installed

* "huff n' puff" VFO stabilizer (for negligible freq drift)

* full output on all bands, (including 100 watts out on 10 meters)

* "beautiful" transmitted audio (not my description, but that of many contacts)

* new HV caps

* cleaned (DeoxIT'd) switches and pots, including band switch (which showed no problems)

* nicely and accurately repainted cabinet (full re-paint, not just touch up)

* new cabinet feet, hardware and carrying handle

* cleaned and detailed front panel and knobs

There is one remaining glitch: the VOX is VERY sensitive and trips too easily unless headphones are used. The anti-vox appears to be at fault.

$475.00 plus shipping from Zip Code 20902

Please contact off-list, if interested. I can ship Tuesday.

Many thanks and 73,

Craig
W3CRR

43367. TS-830s Service Manual typos and revisions

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-14 13:20:48 UTC
From: r_krohne@sbcglobal.net
Topic: 43367 Message: 43367

Group,

Reading through the posts here and elsewhere I have often seen mention of typos in the service manual. Does anyone have a list of the typos and/or their page numbers? The service manual that I have run across for download has "revised addition" on the front page. One manual I have seen for purchase on hybridrestore.com lists a Third Edition service manual. Which manual is the most current and presumably the most accurate?

Thanks,
Ralph (KB1ZYI)

43368. TS-820s display and associated issues

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-14 15:48:31 UTC
From: n4eyz
Topic: 43368 Message: 43368

I'm a relatively new owner of a TS-820s. Been licensed since 1978 and wanted an 820 back then but with a new growing family the money just wasn't there for such a rig. Built a HW-101 and never regretted that move. But still always wanted a Kenwood. I also have a 706MKIIG. Anyway found this 820 last year and just within the past week finally got it on the air. All seems well except a small vfo issue. I'm a little familiar with the display issues that plague the 820s. Mine is pretty stable until I tune below 14.200, then it starts to flicker and blank out. On other bands it will behave somewhat the same especially if I tune very fast. Is this pretty much the same as what most of them do concerning the display problems?

I'm not at all afraid to delve into the rig, but want to be sure this is the same problem. I have basic troubleshooting skills and some equipment. I repaired more stuff my accident than intentional! :)

From: W5RKL
Topic: 43368 Message: 43369

Wayne,

The key here is the same symptoms are occurring on ALL bands at the same dial setting.

The problem, based on your comments, is not a "display problem" that many hams tend to believe. As you said when the VFO is tuned to the same dial setting on ALL bands the same symptoms occur. That tells you the problem is not caused by the display but rather the VFO. The problem is corrosion/dirt build up inside the 820's VFO at the connection between the VFO's variable capacitor shaft and the variable capacitor's frame. This connection is made by a brass "fork" that slides between the capacitor's shaft and frame. I refer to this connection as the Variable capacitors shaft to frame connection.

Do NOT attempt the following cleaning process with the 820 plugged into AC mains. ALWAYS disconnect the equipment from the wall outlet BEFORE attempting any cleaning of the 820. When removing the top cover, use care to ensure you do not break the connection to the internal speaker. The speaker cable is plugged into the speaker bracket, so carefully pull the plug the orient the cable so it's out of your way then lay the top cover aside. Repeat this process in reverse when testing. Do NOT power up the 820 without the speaker connected or an external speaker connected (external speaker plugged into the rear panel ext spkr socket)

Remove the 820's top cover, orient the 820 so the front panel is facing you, the VFO is the square metal enclosure that's in the middle and closest to the front panel. Look on the right side of the VFO enclosure you will see a small cover plate held to the enclosure by 2 small phillips head screws. Loosen the rear screw then remove the other screw. Rotate the cover plate so you can see inside the VFO. You will see the variable capacitor shaft with plates attached. Look to the rear of the capacitor shaft and you will see the fork connection that needs to be cleaned. Apply contact cleaner to this connection then rotate the VFO knob throughout it's travel in both directions, several times. Use canned air (available at Walmart) or compressed air and blow out the cleaner residue while rotating the VFO know "again". Let the 820 sit for 5 minutes or so then power up the 820 to see if the symptoms are still there. Rotate the VFO knob throughout its travel in both directions to be sure. If you still see the symptoms, repeat the cleaning process. This may take you several cleaning attempts to get this connection point cleaned. Once the symptoms are gone, close up the side panel and replace the top cover. Always follow the cleaner's warnings printed on the can. Use generous amounts of canned air or compressed air to remove any/all cleaner residue after cleaning before testing. Always let the equipment sit for a least 5 minutes (see warnings on the cleaner can) before

applying power! Some cleaners are flammable and it only takes a small spark to ignite the cleaner. Never turn canned air UPSIDE DOWN!! Doing so will allow the propellent to escape and if you get it on your fingers, it can cause frostbite burns (the cleaner propellent is very cold!!!). Do NOT use WD-40 as a cleaning agent!!! I hear/read where some hams have been using WD-40 to clean but I do not recommend it!! By the way, WD-40 is "Flammable"!!! DeoXit F5 is a Fader control that cleans and lubricates. It too is Flammable. Craig products such as DeoXit D5 and F5 cleaners, have non-flammable products so check their website. I use DeoXit D5 for cleaning switches and switch shaft bearing detents (does wonders to free up stiff shaft bearing detentes). I follow with light weight lubricating oil applied with a clean Q Tip pressed hard against the bear detente where the shaft protrudes. This allows the light weight lubricant to flow into the bearing detent lubricating the detente. I don't spray the lubricant, the Q Tip pressed against the shaft and bearing detente assembly works best. After applying the lubricant I rotate the shaft several times throughout its travel to allow the lubricant to apply itself to the bearing and detente. Wipe up any excess that may flow on the shaft and outer part of the bearing assembly with a clean cloth.

43371. Question on TS-830S IF Board

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-14 16:24:52 UTC
From: Don Allen
Topic: 43368 Message: 43371

I'm a new group member, and recently acquired a TS-830S. I've owned other Kenwood gear since the mid-70s, but never an 830.

As with any used gear, you "pay your money, and take your chances." Overall, this 830 is in excellent shape, except it has one mod which I would like to address here. If anyone has any ideas what this may be for, please let me know. As you know, the 830 has two IF outputs on the back panel. However, the previous owner has added another RCA jack on the back panel, and the RG-174 coax goes beneath the IF board to a point very near Q19 on the board. The coax center lead is soldered to a pad on the board through a 100K resistor. I haven't removed the board to determine exactly where the tie-point is, as this observation is through visual inspection only from the chassis side of the IF board.

Any ideas what this added jack and mod might be used for? I remember adding such a mod to my TS-520S in the late '70s for an IF output to drive the BS-5 in my SM-220. However, isn't this what the IF Out 1 (low-level) and IF Out 2 (high-level) jacks are used for on the 830?

Tnx,
Don W9CW

Tom,

Although I am not positive, that added connection and socket could have been made to connect the SM-220 with the BS-8 Pan Adapter or possibly an adapter for other purposes a previous owner may have been using.

I suspect you could remove the cable and resistor from the IF board without resulting in any problem(s). However, having said that, if the 830 is operating fine the way it is then simply leave the cable and resistor connection to the rear RCA socket in place. The less movement/dismounting and pulling of plugs from the board, the less chance there is of creating additional intermittent problems such as creating breaks/cracks in PC board foil runs. So, again, if the 830's operating fine then leave it alone!

I misspoke. The rear panel RCA socket, RG-174 coax cable and resistor that may be connecting to Q19 on the IF board is NOT an SM-220 BS-8 adapter as I first thought. Looking at the 830's IF board schematic, it appears that cable and rear panel RCA socket is for connecting external audio processing equipment, something I would not recommend. You can leave the cable in place.

Mike,

That's what I considered, as the two stock IF outputs can be used to drive a SM-220/BS-8. I didn't think of the audio processing possibility, but did think that it may be a mod for use with a Telepost LP-PAN panadaptor for example.

I will just leave it alone.

Topic: 43368 Message: 43377

If I might add to Mikes advice regards WD-40.

DO NOT lubricate the rotor shaft wiper contact with any kind of lubricant.

This can defeat the purpose of this contact by insulating it from its mating machined contact area on the end of the rotor shaft. The whole idea is you want a very high conductive rotary contact for RF currents to flow from the rotary plates to the capacitor frame. This is why they do not rely on the ball bearings and ball race at the shaft end for the RF path. The ball bearings and race is where you want some light lubricant(typically grease and not oil) not at the contact wiper end of the shaft.

The rotor shaft contact wiper is made of Phosphor Bronze and heat treated to give it just the correct spring tension to apply on the machined face of the rotor shaft. Over time especially if the VFO does not get much exercise or is limited in its travel this contact area can oxidize (dark discolored and perhaps greenish color).

Also, you do not know what previous owners have sprayed here. If a lubricant it can be attracting dust. So it is best to follow Mikes good advice and clean with DeOxit and blow out with canned air and DO NOT lubricate. As Mike notes this may take more than one cleaning cycle.

Also, never reach in with a screw driver or other tool and attempt to press on the wiper. You could bend it and/or change its contact pressure. I actually saw this advice on another forum and have heard it recommended on the air. Very poor advice.

Lastly, DO NOT apply any conductive grease to the rotor shaft wiper contact. Some people recommend using a silver or carbon impregnated grease to lube this contact. I dont like the idea of a conductive grease applied inside the VFO where I cannot control possible migration.

In short clean, exercise, and blow out with canned air and then use your radio. This applies to all the Hybrid air variable tuning capacitors.

OK for you real old timers yes Cardwell use to sell a special grease in a small tube. I once had a tube, but do not remember what it was for. I do not know what the composition was and my guess is that it was for the front ball bearing race and not the rotor shaft wiper contact. If anyone has a tube maybe can see if any instructions are on it. I looked at a 1940s Cardwell catalog and did not see the grease listed.

My 3 cents worth.

This sounds like a Phone Patch input. See page 26 of your instruction manual. A factory approved Mod.

Terry,

You are correct, that's exactly what it is! I must have missed that in
the manual. I've noted there are at least a couple of versions of
instruction manuals for the 830.

Topic: 43367 Message: 43380

The TS-830 Instruction Manual and Service manuals are pretty good. They do contain typos that are just that and perhaps translation issues, but generally no where near the number of serious errors that the TS-820 documentation contains.

I call a serious error calling out the wrong test point, the wrong adjustment point, and the wrong acceptance criteria.

Examples of typos would be adjust the Carrier "Contr-L" or the Noise "Blankes". These are of no consequence.

A serious example is on Page 28 of the Instruction Manual Sect 6 Maintenance Section which tells you to adjust TC-2 Trimmer to balance the Carrier and the correct Trimmer is TC-3. TC-2 is the VBT carrier osc frequency adjust. Now what will you do if you have already adjusted TC-2 and didnt get any change in carrier null? How will you get TC-2 reset? Not the end of the world but not what you needed.

To avoid this kind of thing dont just adjust the pot or trimmer cap that is called out. Look at the schematic and see if what you are being directed to do makes sense to you. In the above example you would have located the Balanced Modulator ring diodes and seen that TC-3 is the proper trimmer cap and not TC-2. If you had gone to TC-2 on the board you would have noticed a crystal sitting next to it and no ring diodes. Warning bells should go off as should be no crystal associated with the Balanced Modulator and trimmer cap and diodes should be in close physical proximity.

An additional concern is that there are errors on the schematics and on the silk screen labeling on the boards. It depends on what generation board you have installed. Boards are commonly swapped out. There are definite differences especially on the AF and IF boards.

Examples include R199 on the IF board that feeds the AGC bus line may be labeled as R149. There may be two R149 labels on the IF board. The 2nd and correct resistor is at the Speech processor Limiter IC.

There are several electrolytic capacitors that are installed reverse polarity (plus lead to chassis ground) and the silk screen and schematic shows them mounted with Negative lead to ground. They are installed correctly and the schematic and board labels are wrong. If you find a cap installed reverse of the schematic or board labeling do not assume that the as built configuration is wrong. Study the circuit or come back and ask before you change it to match the schematic.

Also there are errors on most of the schematics. Some minor and others not so minor. Look at the SG relay contact on the HV rectifier board and the SG switch and see if the contact is shown correctly for the SG off. Should it be a NC or NO contact? The schematic is supposed to reflect the rig in RX mode with no signal at antenna input. So is SG switch shown correctly?

Step 2 of the Service manual tells you to adjust the "Base" current and it means Bias current. It is a typo, but should say adjust the Bias Voltage to obtain a Plate Idling

current of 60ma. You dont adjust Bias Current.

The acceptance waveform for VBT adjustment in Step 23 of the Service Manual is reversed. The correct waveforms are shown in Step 22.

RF detector voltage divider resistor is mislabeled. Called out as 10 ohms and is 10K.

There are others. I do not have what I would consider a complete list compiled that I can send you. I just mark up my documentation as I find them.

As far as I know the 3rd Edition of the Service manual is the latest.

Sorry so long.

Terry K9TW

The service manual that I have run across for download has "revised addition" on the front page. One manual I have seen for purchase on hybridrestore.com lists a Third Edition service manual. Which manual is the most current and presumably the most accurate?

I agree but it's not connected to Q32 as the manual states but rather
Q19. R111, C103 and C104 are no where near to nor do they connect to the
input of Q32.

In my original post, I stated Q19. And, that's the transistor specified on Page 26 (upper-left hand side) in my instruction manual. Here's the paragraph in question verbatim:

"For those operators who desire a Patch input similar to the TS-520S or TS-820S, an input connection and terminal must be added at the Mic input preamp circuit. Use a 100k Ohm resistor in series, with a 10k Ohm to ground on the input side of teh 100k Ohm resistor. Use shielded line, and connect as follows:

On the IF unit X48-1290-00 install the fixed divider at the junction of R111 10k Ohm, C103 100pf, and C104 1uF (input of Q19). Add an RCA jack at one of the predrilled hole on the rear panel for input."

Q32 is not referred to in my manual within this subject area... I wonder how many instruction manual revisions exist?

This instruction manual is 25312 B50-2738-00 (G) (K)

As Terry said, there are mistakes in the manuals. The 830 pdf operator's manual I have says "Q32". The following is what's stated on page "25" in the pdf copy of the 830 manual I have:

"On the IF unit X48-1290-00 install the fixed divider at the junction of R111 10K, C103 100pfd and C104 1ufd (nput of Q32). Add an RCA jack on one of the predrilled hole on the rear panel for input"

Mike,

Many thanks for the repair instructions. I will do exactly as you have said. I remember reading probably on this board concerning that connection problem. That's what I'll do. Thanks again!

Mike:

Take a look at the manuals on Dick Housdens W0NTA website. He tries to get latest revs and uses some means to enhance the quality and brighten them up. I have more than one hard copy of the TS-830 instruction and service manuals, but I also downloaded PDF copies off Dicks site as well.

Well, this unit was in storage for about 10 years. I decided to set the station back up and the SM 220 was the last item to go back online. It worked fine for a while, now it has little or no display on the screen.

43390. Getting close with the 820

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-15 02:15:31 UTC
From: Barry
Topic: 43390 Message: 43390

A friend in our ham group did a great job yesterday getting my 820 transmitting after spraying some contact cleaner into the Load and Drive areas. I figured I would open it up today and clean more of it.

I pulled several connectors and cleaned them. Plugging it back in the display came up showing 9.000, so it looks like I'll be opening it back up tomorrow to see what's not together tightly.

Is there anything in particular I should look for?

If you have Dim display it sounds like you have problem with the -1300HV supply. It provides Intensity and Focus potential for the CRT. Do you have a meter that can measure this level?

If the voltage is low or missing the common failure is the HV filter caps and diodes. Look on the schematic and you will see D112 and D113 doubler rectifiers. Need to test them. Also most likely have bad filter caps C139 and C140 .1 uf at 1KV wvdc. Will have to use subs for the diodes. Can place regular silicon rectifier diodes in series if you cannot locate suitable subs. TV flyback diodes will work.

If you cannot measure the voltage then just test the diodes and caps and replace. If you cant test then just replace as the caps have some age on them.

NTE-525 2000 piv fast recovery diodes will work, but pricey. Radio Shack on Ebay has them listed at $7.60 each. Use Poly Film caps. Mouser should have them.

I see that there are NTE-638 TV flyback damper diodes rated at 1600PIV @2.5A listed on Ebay (Radio Shack) for $2.06 each with free shipping.

As I mentioned in first post OK to put two common 1000piv silicon diodes in series in each leg, but a single diode is a cleaner installation.

HI Michael,

You will most probably find it is the HV PIO caps, these tend to leak or dry out I have repaired a number of these, but it could also be the diodes or bad solder joints in the HV area. I have tracked down NOS PIO 1kv and 2KV caps in the past from EBAY and replaced them all, so far no apparent issues after 2 years. The PIO caps when they leak are pretty dangerous and usually are a carcinogenetic substance. I have seen where people have replaced the PIO caps with polyester caps, they seem to work OK. I'd suggest replacing all the HV PIO caps with same values and voltages. But most importantly make sure you discharge the HV before touching that circuit, it stings quite a lot! Let us know how you go and we can help you out.

Michael,

When you first power on do you see a trace? If you do and then it starts to fade it will be C139 1KV, C140 1KV, C137 2KV, C138 2KV or C135 2KV every one I have repaired with this symptom it has always been one of theses caps, I always replace all three. If you do have a trace and it starts to fade you can use a can of freeze spray on the centre of the HV and give it a short blast, usually the trace will come back and then fade again.

Terry and others,

I checked W0NTA's website for manuals. I downloaded the 830 and 820 manuals to compare to the ones I have. I must say W0NTA's manuals are much better, cleaner, better fold out pages, especially the 820 service manual! I plan on comparing all of W0TNA's manuals against the manuals I have.

While comparing the difference in manuals, I also see where page 25 in the W0NTA 830 manual shows the phone patch mod is connected to the input of Q19, NOT Q32 as it is in the 830 phone patch mod mentioned in the 830 manual I had. I am not surprised at the difference in the manuals since I've had to reference manuals over the years and have noticed quite a few errors in manuals, whether service, operator, and/or assembly manuals. The key is to have a good understanding of what the mod does. For example, in the case of the phone patch mod in the 830 manual that provides a similar phone patch connection that's in the 520, the incorrect 830 manual says to connect to the input of Q32 on the IF Unit board. If one looks at Q32 on the IF Unit board schematic one will notice it has nothing to do with "audio"in the speech amplifier's signal path to the BM (Balanced Modulator). Q19, on the other hand, is in the speech amplifier's signal path to the balance modulator and when one compares the 830 mod to the factory phone patch circuit in the TS-520andknowing what a phone patch actually does, one would see the mistake made in the 830 manual where it references connecting the 830 phone patch mod to the input of Q32 and that the input to Q32 has nothing to do with phone patch audio.

Mike:

Yes not to knock what Gordon has done for all of us in the free manual area, however, Dicks manuals are top shelf. I think he and Mark Gilger have collaborated on these?

Yes Q32 is the Moni buffer amp and takes a very low level sample of the modulated 8.830Mhz TIF amp output and demodulates it. Cant imagine why any mod would want to inject anything at input of Q32 and certainly not audio. Of course have seen some pretty strange mods. By the way I know you understand this Mike but for those who may not just a reminder if you are going to use the Moni feature that you must have the Heaters on and the Drive Control peaked so you can get ALC action at Gate 2 of the TIF amp. Otherwise the audio you will hear in your headphones will not be the quality level you want to hear.

Yes I always tell people never just blindly do what any of the Kenwood (or any other manufacturer) manuals directs you to do. Need to ask yourself what is the intention of the step? What is the expected outcome? Does the Test Point make sense? Does the Adjustment Point make sense? Does the Acceptance Criteria make sense? This last one takes some level of experience. For example, you have to know that Carrier Osc level or LO levels are not typically 50mv. Also helps if you can recognize a Balanced Mod or Product Detector configuration when you see it on the schematic and on the IF board. Just takes time.

If you have not downloaded the high res TS-820 schematics from Ken K4EAA site should do that as well. I have them on my desk top.

Terry, I have the high res TS-830 schematic, in color. That's the best schematic to use when identifying components and for troubleshooting an 830. Anyone who has not yet downloaded this schematic yet intends on servicing their 830, they should download and study it.

Gordon has provided an excellent free manual service on his website, I still have a lot of manuals from his website and I intend on keeping them. The ones I will discard are the ones that I got from other websites that are difficult to read, fuzzy, and incomplete.

Yes I have the TS-830 color one blown up and laminated and then a couple of non-laminated ones and one of them is my working copy that has lots of mark ups and notes and is starting to get pretty ragged. I have one spare new one from Ken K4EAA still in the mailing tube so I am good for a long time.

Also, I have the blown up TS-520 laminated (gift from Jimmy WB2KNR) and TS-820 blown up and laminated, but not in color. Just got the TS-530 series from Dave VK5PDL as a nice surprise gift.

I hate the PDF schematics that are cut in two or three sections that find commonly on other sites. The cut or split often doesnt overlay properly and almost always is the point you want to look at. I have had to deal with that with Heath, Drake and Collins schmatics. A real pain.

How do I remove the plastic cover on the RL-1 relay so that I can inspect the contacts on the relay? I push the cover gently to and fro with my hands, but it will not let go.

Thanks.

Gently pry the cover away from the base at the two small tabs; one each on opposite sides. They are difficult to see.

The cover does not come off easy as the fit/clearance at the tab area is very tight. It is not hermetically sealed but darned close. Can try a small thin flat blade screwdriver or X-acto hobby knife (I hate to see blood on the audio board!).

I do not recommend that you remove the cover. The contacts are small and it is easy to damage the armature leafs. Any cleaning you can do will not last long in my experience. You are far better off to buy a replacement relay from Ken K4EAA or from Jim at HybridRestore while the sub relays are still available.

A replacement relay will eliminate about 90% of the intermittent conditions you may be experiencing. Not a difficult task to replace one. Should last another 30 years.

My 530 all of a sudden shows this on the display. This is the only issue. The rig tunes frequencies normally.Rx Tx functions normally. Reflowed the solder joints, and feed throughs on the counter board during an overhaul 9 months ago, with no issues till now. Haven't opened the rig to troubleshoot yet, but any suggestions would help. Thanks. Eric KA2PVT

I am curious why you reheated the solder connections on the TS-530 counter board? It is very different configuration from the TS-820 and does not suffer the same problems with vias. I assume you were having some sort of display problem?

Try gently pulling and re-seating the 5 molex connectors on your counter board. Pull straight up and avoid side to side rocking force. Try loosening and re-tightening the board mounting screws.

I was able to get the 820 responding pretty well, actually, after everybody's help and patience with my questions. I went to a friend's house Saturday who helped me open it up and clean some spots that I didn't already, and now it is actually transmitting pretty well.

After cleaning more of the connectors Sunday night I had inadvertently incorrectly set one of them, so opening it and resetting the connector last night allowed me to fire it up and transmit. I caught a couple of guys talking around 28.361 after hardly ever hearing anybody on the band, so the cleaning helped me talk to them for a little while. Another guy way off heard me really well, so I'm thinking about buying some new tubes to really get this thing going.

Thanks, everybody, for being willing to help out with your vast knowledge and skills. Your help has opened up a new passion, and I'm liking this old school rig in a big way.

Topic: 43356 Message: 43409

After installing the new tubes dont forget to set the idling plate current to 60ma in SSB mode with Mic gain turned all the way CCW. Key rig and adjust the bias voltage adjust trimmer pot for 60ma indication with meter selector switch in Ip position.

Also will need to Neutralize. You do this around 21.250mhz. There are different instructions on how to do this in your operating manual and in the service manual. The service manual has you pre-set the neutralizing capacitor plates to half mesh and then load rig to max output. Then flip SG switch off and adjust neutralizing capacitor for minimum RF voltage across 50 ohm dummy load.

No reason to pre-set the cap to half mesh. OK to load to full load in dummy load and then turn off SG switch and leave Heaters turned on. Not likely to take off on you and position of the Plate Load and Plate Tune caps will affect the adjustment.

You will need RF probe and VTVM or O-scope or another receiver to sense the RF voltage and adjust the null. I use a PL-259 with two 100ohm 1/2 watt resistors in parallel across it. Gives place to connect your RF Probe to measure the voltage drop across this mini-dummy load. Key the rig and adjust the neutralizing capacitor for minimum voltage. After adjusting for a null re-adjust the Plate Load and Plate Tune controls for a peak in voltage while monitoring the RF voltage across the dummy load. Not unusual to get more RF voltage. Adjust the neutralizing capacitor again for minimum RF voltage. You can adjust Plate Tune and Plate Load again to see if you get another peak but usually two iterations is enough.

CAUTION: Make sure you use an insulated tool to adjust the neutralizing capacitor. Some folks make them from oak dowel rod. I just use a screw driver that has a blade the fits the slot very well and have the shaft and handle insulated with couple of layers of heat shrink. If you make one from dowel give your self a handle as the neutralizing capacitor turns stiff by design.

They recommend that you do the adjustment with the PA cage cover on which isnt as easy as it could be inserting the tuning tool at an angle thru the provided hole and not being able to see well what you are doing. For that reason I do it with PA cage cover off and just exercise extreme caution around the tube anode voltage.

If you are uncomfortable doing this adjustment might be a good one for your experienced Ham friend to help you with for this first time.

Make sure you turn SG switch back on when done.

I forgot to mention that with SG off and flip to Send you may want to first re-peak the Drive control for max ALC indication to have a decent RF voltage level across the mini-dummy load to work with. Then you can insert adjustment tool into Neutralizing capacitor shaft slot and adjust for minimum rf voltage on your VTVM, O-scope, or signal level on other receiver S-meter and speaker audio.

43413. TS-820 frequency stability issues

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-16 21:46:11 UTC

Topic: 43413 Message: 43413

Hello again everybody.

Thanks for the replies in my previous posts; they've been very helpful.

Following the advice from my previous posts, and also closely following some of the other threads like "TS-820s display and associated issues", I went ahead and cleaned all boards in the radio, removing them one at a time, cleaning all pins and ground contacts, and mounting them again. After that, because the frequency would still not sit still most of the time, I proceeded to clean the VFO several more times, following Mike's helpful tip to focus in the rear wiper, now that I know what it is. ;-)

Current status: The frequency is now stable most of the time on bands 20-160m. After leaving it on for several hours (and sometimes I feel it doesn't matter how long it's on for), it starts jumping around maybe 5kHz up and down, very quickly. And sometimes the jumping around goes to the big leagues, where I think the PLL gives up and the frequency does not even stay on the same band (20m is the quickest one to unlock).

On the other bands (15-10m) the PLL never locks. I think I've only seen 15m lock once or twice since I've owned this radio (~3 months), and never on any of the 10m band segments.

So, it still looks like grounding issues, right? I'm just not sure what else to clean. The only thing I can not reach well to clean is the band switch, so not much deoxit is reaching it. I'm not sure how to take the switch out (service manual does not show that), or somehow open the space around it so I can get really close to it to be able to clean it.

I welcome any more advice on what I should try next. :-)

Cesar,

I will assume that you removed, inspected, and cleaned the boards in the "counter unit." That's the box that supplies the info to the digital display tube. This item has been, at times, a real pain to 820s owners. Have you done the recommended resoldering of the "through holes?" These holes connect one side of the boards to the other...they look like solder pads and are supposed to have solder connecting them from side to side. Often over time, these "connections" fail. May I suggest that you removed the unit, and do the repair..if not done already. Also while the boards are out...inspect under BRIGHT light and magnification ALL the solder connections/pads. Check page 40 of the 820S service manual as it has some trouble shooting info regarding this problem

Barry,

Making a simple "dummy load" for neutralization is rather easy. As Terry(k9tw) stated..you can use a PL259 connector and a
couple of 100 ohm 1/2 or 1 watt resistors in parallel to get 50 ohms..use this "dummy load" only AFTER you have tuned up for
max power..on 21.225Mhz and a "regular" dummy load. USE an INSULATED tool..or one of wood or plastic! A simple RF probe/detector and a VTVM or DMM will work fine. I like usinga VTVM, as it's got a nice big face and needle...and all you're looking for is a "null" or the lowest reading...a DMM(digital multi-meter)
works too...just a bit more difficult. Make sure to remember to turn off the "SG" switch before you use the "small dummy load"!!!!!!!! and then remember
to turn it back ON...or you will not transmit.

In case someone prints this and saves it there is one correction.

After making the initial null adjustment DO NOT adjust the Plate Load control. Leave it where it was for max CW rf output into a 50 ohm dummy load. Only adjust the Plate Tune capacitor for a peak in RF voltage across the test dummy load and then repeat the final neutralizing capacitor adjustment for minimum rf voltage.

Terry K9TW

"After adjusting for a null re-adjust the Plate Load and Plate Tune controls for a peak in voltage while monitoring the RF voltage across the dummy load. Not unusual to get more RF voltage. Adjust the neutralizing capacitor again for minimum RF voltage. You can adjust Plate Tune and Plate Load again to see if you get another peak but usually two iterations is enough."

Thanks Joe, I will look into that. I wish I had am external frequency counter to make sure the problem is only with the display unit.

> Hello again everybody.
>
> Thanks for the replies in my previous posts; they've been very helpful.
>
> Following the advice from my previous posts, and also closely following some of the other threads like "TS-820s display and associated issues", I went ahead and cleaned all boards in the radio, removing them one at a time, cleaning all pins and ground contacts, and mounting them again. After that, because the frequency would still not sit still most of

the time, I proceeded to clean the VFO several more times, following Mike's helpful tip to focus in the rear wiper, now that I know what it is. ;-)
>
> Current status: The frequency is now stable most of the time on bands 20-160m. After leaving it on for several hours (and sometimes I feel it doesn't matter how long it's on for), it starts jumping around maybe 5kHz up and down, very quickly. And sometimes the jumping around goes to the big leagues, where I think the PLL gives up and the frequency does not even stay on the same band (20m is the quickest one to unlock).
>
> On the other bands (15-10m) the PLL never locks. I think I've only seen 15m lock once or twice since I've owned this radio (~3 months), and never on any of the 10m band segments.
>
> So, it still looks like grounding issues, right? I'm just not sure what else to clean. The only thing I can not reach well to clean is the band switch, so not much deoxit is reaching it. I'm not sure how to take the switch out (service manual does not show that), or somehow open the space around it so I can get really close to it to be able to clean it.

43418. Mostly good news on recently-acquired TS-830S

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

Hi,

I've been tinkering with the latest addition to the herd, a TS-830S.
I bought it (knowingly) with the description that it was working fine, and then one day - voila! - no TX or RX.

When I received it, I checked the paramaters Terry recommended - all was well. Also did a visual and "smell" test, with nothing obvious noted. I did find the "SG" switch on the rear apron in the "off" position - that'd explain the "no TX issue".

Put the covers back on, plugged it in and eureka! - got receive audio! Subsequent power cycles have seen the lack of display being illuminated.

A carefully-placed, calibrated sharp rap to the cabinet just above the display brings the display to life (in all cases so far).

My question is: Aside from opening the rig back up to re-seat connectors and/or loosen/tighten board mounting screws, is there anything that is 830-specific that I should be looking for?

Thanks,
Ken

Sounds to me like the PLL Unit is changing to an "Unlock" state. I say this because you "hinted" that by tapping on the cover the display comes back along with receive. If the 830 receive and transmit fails when the display goes dark then tapping on the cover brings the display back along with both transmit and receive, the problem is not in the Counter Unit or display but rather the PLL Unit is changing to an "Unlock" state. This can be caused by a number of reasons from loss of B+ to the PLL Unit, loss of the VFO and/or CAR signal to the PLL Unit, broken/cracked foil runs on the PLL Unit board, etc. I would check all voltages (see the 830 service manual) to ensure they are present then look for broken/cracked foil runs starting at the plug pins. Make sure the mounting screws are tight since the board's ground is on the edge of the board and at the mounting screw holes on the foil side. You can clean the plugs by pulling "straight up" then pushing the plugs straight down. This results in "scrubbing action" occurring in the plug as the pins slide into the plug. You can use a cotton swab wet with contact cleaner to clean the pins before you put the plug back on.

Read and adhere to the warnings on all contact cleaner labels.

I forgot to mention that quite often cracks/breaks in foil runs occurs when people think they should reheat solder connections for no reason, quite often because someone told them to. Unless there is clear evidence of a bad solder connection, do NOT reheat the connection! The foil runs on the PC boards are very thin and can crack/break when excess heat is applied. Quite often the crack/break cannot be seen, some crack/breaks occurs under the solder pad that you can't see. If you have an analog ohm meter and you suspect there's a break/crack in a foil run, using the ohm meter to test for continuity over the foil run or from a pin to a component lead. A break will show up as an "infinity" reading on the ohm meter. You may be able to inspect a suspected break in a foil run by using a high intensity light shown on the component side and look on the foil side using a magnifying glass. Not only can you find some foil breaks/cracks that way but you can also find shorts due to slivers of solder or very thin wires that lay soldered across points they should be. Don't think this happens? Think again!! It happens quite often.

All great information, Terry. I certainly appreciate it. No doubt I will for sure get my friend to help oversee this operation.

Is it okay to replace the driver tube only and wait on the finals? Just plug and go?

And how are you feeling after the hospital stint? I've been praying you'd adjust well to whatever you have had to deal with.

Hi Group Thank you that all those that had suggestions for my 820S Display error.

I removed the counter module and the two boards within. Did a close inspection of the top and bottom for something that maybe wrong. The previous owner(s) had already soldered the feedthrough's using fine bare wire(s).
Hence the problem! 3 feedthrough wires were not trimmed close for the excess wire(s) were shorting to a adjacent pad(s)for atleast 2 of the miscut.
I trimmed the excess wire, then washed both top and bottom of the boards and re-inspected to be safe. Then I lightly sanded all jacks,cleaned then treated each with DeOxit Gold.

Reinstalled......problem fixed!!! The person that did the feedthrough's had snake bit himself by NOT inspecting his work. HE
added a new problem.

Now the rig is working like a champ......displat too!

Terry, any chance this procedure works for the 830S, also? If not, have you done a similar procedure outline for the 830S? If so, would you mind repeating it here? I can also do the legwork if you would let me know the approximate date you posted it.
Thanks,
Chris

Chris:

Use the same procedure on all Hybrids or any boat anchor for that matter. Only exception is with introduction of the TS-530/TS-830 Kenwood changed the frequency at which you neutralize from 15 meters (around 21.3 mhz) to 10 meters (around 28.8 mhz).

Since the rigs are multiband 160 thru 10 meters the original 21mhz was selected in an attempt to get some benefit across 20 meters thru 10 meters where the tubes are most likely to oscillate at or near the fundamental frequency. Some of the new linear amplifier manufacturers still recommend 15 meters for same reason Kenwood originally did.

Truth is neutralization is really only 100% effective at the band and frequency it is performed at and the place you are most likely to have the tube oscillate is on the highest operating frequency. By the time you get to 40 meters the reactance of the internal plate to grid capacitance is so high it is very unlikely tube will oscillate so if you do not operate on the higher bands (15 and 10 meters) very unlikely anything will happen if you do not neutralize the new replacement tubes. Truth is neutralizing at 21.3 mhz is a compromise.

I had a fellow write me couple years ago to tell me he never neutralized any 6146 tubes he installed and never had tubes take off. He thought it was a lot of hype. I wrote back and told him yes that is possible but suggested he didnt operate on 15 meters or 10 meters and he was taking some risk if he did operate on those bands especially 10 meters. I asked him why he thought Kenwood would go to expense of adding the neutralizing circuitry if not needed. He responded to say he had no antenna for 10 and never operated there, but did operate on 15 and had no problems. I suspect his neutralizing capacitor was set reasonably close and that the Cgp inter-electrode capacitance from tube to tube brand was pretty close to same value.

Point is if you have not neutralized the tubes in your TS-830 you are OK operating on the lower bands.

This is easy to see if you work the reactance of the 6146 plate to control grid inter-electrode capacitance. Xc = 159 x 10 to the -3/F x C. The tube data sheet shows Cgp = .22pf. At 10 meters 28.8mhz the reactance is approx 25k ohm. At 40 meters 7.2mhz the reactance is approx 100k ohms.

Adjusting the Plate Tune control after first null is a procedure refinement that some folks dont use and Kenwood doesnt describe in the manuals. From practice I know you can get a better null by re-adjusting the Tank. So at 28.8mhz you should end up with max RF output occurring right at Plate current dip. As you move away from 28.8mhz to lower bands and lower in frequency the plate current dip will not occur precisely at max RF output. This is OK. Max Rf output will occur at Tank circuit highest impedance as opposed to where the Tank is pure resistive. This is why I always recommend to load to max RF output without exceeding rated Ip. You will be slightly off resonance, but PA is running more efficient at this point.

So short answer is to neutralize your TS-830S use the same procedure I provided and change the frequency from 21.3mhz to 28.8mhz.

Just put the twins on the air,what a pair. Have a coupla of questions.
the r-599d has a aux position on the band switch. the manual talks about putting in a crystal for WWV and peaking it with the aux trimmer. Why couldn't I put a crystal for 17 meters in ,peak it and listen to 17? just listen ,no transmit.

Hello all,
I acquired a 530 as a parts rig and it is in such good condition I do not want to part it out. Serial no. is 3XXXXXX. Better shape than my bench 530 I use for experimentation. After usual switch and molex plug cleaning I checked all voltages at plugs on each board and all checked OK. The display comes on momentarily on start up but fades like the dying embers of the last beach bonfire of the season. I did check voltage on the counter board where I had access but I did not do a thorough check. Plenty of juice flowing. Have never encountered this before. Tried a known good counter board and it did the same. Also, after the first fade out the display will not come back after repeated switch on's until I remove the board and re-install it again. I have scrubbed the pins repeatedly. The rectifier board is pristine and all voltages are present and correct. Have not attempted transmit until this is resolved. What do you have to tell me before I remove the RF board and begin band switch repair. I do have voltage on the band switch. Anyone ever see this before?

I have been out of commission and have not had much time to be in the shack. I have a few projects I am working on but thought I would take some time to try and save this 530 from the cutting torch.

Thanks, 73, K5HFG

1. Are you saying you cleaned the 5 counter/display board Molex connectors?

2. Does it do this on all bands?

3. Do you have normal receive?

4. Do you have good 12vdc at Conn 1?

5. Do you have good -6vdc at Conn 2?

6. Should also have good low resistance ground from Conn 2 pins 2 and 5 to chassis ground.

7. Trying a known good counter/display board is telling you something. Besides dc power and ground you do not want a BLK or Blanking input. The blanking pulse originates from the PLL when it is unlocked. Normally it just blanks the display. I have not seen it cause a display to slow fade. If you have normal receive this sounds more like a problem with dc supply or ground. I have seen one bad -24vdc T-power supply, but cant remember it causing the slow fade? Maybe bad caps in the t-power supply pi-filter? I am guessing now.

Get on -6 and watch it as you turn on rig and see if it starts and remains stable.

I goofed better to monitor 12vdc input with power on.

-6VDC was produced from two different display boards so only thing common would be the 12vdc input and ground that is used by each T-power chopper transistors and T1 windings.

Cant be problem with -6vdc supply unless there is something pulling it down at Conn 2 Pin 12 or loads it supplies off the display board.

So still monitor -6vdc on power on and add 12vdc as well.

Hi,
Well, if you have no receive, I would guess your problem is a lack of one of the PLL/VFO/VCO/Car that feeds the board, probably no or low VCO. Especially since a known good board doesn't work either. That would indicate to me it's not the counter/display board.

If a counter is bad, it won't prevent receive from operating. I've got an 830 on my bench right now with display very weird, like this-- _.___.0 -- but receive works fine.

I'd check to see if VCO is getting to the RF board, and then the 8.83 car, and VFO. They all have to work for receive, and display.

I think that's your clue.

Terry,
1. I cleaned all molex connectors
2. It does it on all bands
3. I have no discernible receive on any band(Band Switch?)
4. good 12vDC (rock steady from switch on to switch off)
5. good -6vDC (also rock steady from on to off)
6. Good low resistance ground on pins 2 and 5 on conn 2
7. -24v supply seems OK as I have checked the voltages at Q12 and 13

I suspected an unlock situation but am not familiar with the PLL enough to know what to do but I did not think the fading would result from that. I think it would be either locked in or unlocked. But, i only think that. Not sure. I thought I better get some help.
I did accidentally get probe on R34 lead and it is pulsing according to my DVM.

I will get back to it later this evening. Right now I have some grandchildren standing around me and I can not answer their questions fast enough and maintain focus on the rig.

Thanks for your help,
Don K5HFG

The problem is that you need the associated tuned circuitry for that band to work, ant coil/cap etc and mix coil/cap etc. You might be able to change the cap that goes with the ant coil and mix coil in WWV position so as to get them to resonate in the 17 band. Sounds like a lot of work though.

Dale,

You will need the appropriate 17 meter AUX "ANT, RF, and OSC" coil plus the correct crystal frequency to listen to 17 Meters. The R599D manual shows the ANT, RF, and OSC coil part numbers plus the crystal frequency to listen to 15Mhz WWV in the aux position. I can't say with any certainty but you may be able to modify or adjust the 15Mhz WWV coils plus install the appropriate crystal to listen on 18 meters.

Hi Dale:

I bought a TS-830 from you maybe 2 years ago now. Still have it as a spare rig. Do you still have your Hex beam? I spend winters at Fort Myers Beach and remember coming to your canal home in Cape Coral.

Will let the 599 experts help you. Just wanted to say hello.

OK Don grand kids come first.

This is why I asked you about receive state. It sounds like you have lost your VFO signal to the PLL board. Normally when this occurs your BLK at Conn 2 Pin 4 goes from a high state of approx 4.6vdc to low state ie Zero volts and the display blanks, but does not slowly dim.

Of course with no VFO input then no VCO output to your RIF mixer on RF board and no RX.

Go to Conn 2 Pin 4 and measure the BLK voltage. With Display off should read Zero.

Go to PLL board and gently plug and unplug Conn 5 at rear of PLL board. This is the input from the VFO. If you can measure the VFO signal it should be approx 200mv and depending on where VFO dial is at from 5mhz to 6mhz.

If no VFO signal check your 9vdc from the AVR board. It is rare for the molex connector on rear of VFO to be bad. More common for the 9vdc supply to VFO to be interrupted at the DIN micro switch at the External VFO Din connector on rear panel. Assuming you have good 9vdc at AVR board then try cleaning and exercising the DIN switch.

Dale:

OK hope to get back this winter, but we are helping my daughter by watching our 5 year old grand daughter. We normally come down in early Nov and go back by 2nd week of April. I went to Tampa hamfest and the local club has a regular swap meet in a park not too far from you as I recall.

We rented our place out this past season for the first time and I dont enjoy being an absentee landlord. Dont want to have to do that again.

If we get down plan to visit Ken Kempski at Sarasota and will give you a call.

OK Terry,
I pulled the PLL board in disgust and found several traces almost completely absent. No sign of burning but they are not there. Bare pins sticking thru the holes in the area of Q15 and 16. I doubt I will be able to repair it because it is so small. So, I replaced the board with an untested spare I have.
After that I checked BLK voltage and it is zero as you said it would be.
I then began the check at PLL conn 5 VFO pin and have 212mV. But it is not stable. The molex pins are wobbly so I repaired that and cleaned and exercised the micro sw at the DIN plug which by the way has a steady 9v but the switch is not stable. I spent an hour or so working it in and out and right now the voltage is stable (I am using the scope to check VFO voltage and freq.) The freq. is 5.458 so that is good. I had checked the AF board for 9v and 3.2v previously so I knew they were good. I also checked the VFO to make sure the output was correct and it is 203mV.
This is my plan for tomorrow evening: I will replace the PLL board with the board in my bench 530 because I know that one is good and continue to trace for the problem. I am hitting the shower and sheets for now. Got to get up at 4 AM for work. Thanks for your help today.
I will give it what for tomorrow evening.

> > > >
> > > > 7. Trying a known good counter/display board is telling you something. Besides dc power and ground you do not want a BLK or Blanking input. The blanking pulse originates from the PLL when it is unlocked. Normally it just blanks the display. I have not seen it cause a display to slow fade. If you have normal receive this sounds more like a problem with dc supply or ground. I have seen one bad -24vdc T-power supply, but cant remember it causing the slow fade? Maybe bad caps in the t-power supply pi-filter? I am guessing now.

Don,

Check all input voltages to PLL as Terry suggested, also have a look at the foil side of PLL board conn2, have seen this cracked and causes similar issue. Also I have seen where CB mods have been attempted and usually wires are cut and soldered back together but they usually don't know how to terminate two wires properly and they break down and cause this issue. IF possible check C91 and C92 only seen this once, Q15 was also dead on this unit.

Don just saw your last post re pulling good PLL board and trying out in this radio. Whilst this will give you some good info, I did this with an IF board some months back and didn't know at the time that the new board that I tried was from a later model and had circuit upgrade which gave me false information as it corrected the original fault and I wasted a lot of time concentrating on the faulty IF board rather than looking for the real issue. Food for thought

Subject: [TS-520_820_530_830] TS 530S No display or receive

Hello all,
I acquired a 530 as a parts rig and it is in such good condition I do not want to part it out. Serial no. is 3XXXXXX. Better shape than my bench 530 I use for experimentation. After usual switch and molex plug cleaning I checked all voltages at plugs on each board and all checked OK. The display comes on momentarily on start up but fades like the dying embers of the last beach bonfire of the season. I did check voltage on the counter board where I had access but I did not do a thorough check. Plenty of juice flowing. Have never encountered this before. Tried a known good counter board and it did the same. Also, after the first fade out the display will not come back after repeated switch on's until I remove the board and re-install it again. I have scrubbed the pins repeatedly. The rectifier board is pristine and all voltages are present and correct. Have not attempted transmit until this is resolved. What do you have to tell me before I remove the RF board and begin band switch repair. I do have voltage on the band switch. Anyone ever see this before?

I have been out of commission and have not had much time to be in the shack. I have a few projects I am working on but thought I would take some time to try and save this 530 from the cutting torch.

Thanks, 73, K5HFG

Dave,
You caught me just before bedtime. I am aware of the different revision boards and always compare before swapping out. I generally do not swap boards but as a last resort. The PLL is new teritory for me but am determined to find the problem. I have good readings all over but the problem still eludes me. I am not confident in the spare PLL board as it is untested by me. That is why I am doing it. Thanks for the heads up. By the way I think I remember you trying to talk me into repairing a 530SP face. Just wanted to let you know I found a pristine replacement and it looks good on my rig. I have the old face under the bench and may just give refinishing a try.....Good night OM.

Don:

If you have good VFO level and VFO frequency then there was likely a problem on the spare PLL board causing BLK to be Zero although I dont think I have ever subbed a PLL board that did not work to some degree.

It all starts at Q40 RF Mixer. With the external VFO signal as the RF input at Pin 2 and the Carrier Osc produced on the board as the LO at Pin 5 this Mixer produces the sum frequency of 14.xxx mhz which is fed to BPF-2 and so on.....

It looks like you now have good VFO input level and freq so the known good PLL board should result in a nominal 5vdc on BLK line and the display should be lit and you should have good VCO signal level and good receive assuming no other issues outside the PLL board.

Only other external inputs you need to the PLL beyond the VFO signal is the 9vdc regulated supply and mode switch inputs at Conn 8 and the 8.4vdc bandswitch voltages from RF board to the diode BPF switching matrix at Conn 1.

It is unusual that you would be missing all bandswitch inputs at Conn 1 and all mode switch inputs at Conn 8.

Let us know if good board does not result in display lit and receiver alive. Do not remove good board until you have determined what external inputs are missing.

You can confirm Conn 8 inputs good by measuring LSB and USB Carrier Osc signal level and frequency at Conn 7.

OK Terry,
I will work on this over the weekend. I am hoping for success after sub of PLL board. Now I have good notes for the PLL board work in case I run into this problem again. I am sorry I did not check boards before start of checks but the board looked so good from the top I did not suspect any problem with it. I have learned a valuable lesson. I will remove and examine boards when a problem is found before going any further. Would have saved several hours if I had done it in the beginning. Will report back this weekend all findings.

Thanks All,
Don K5HFG

Dale,

You will need the appropriate 17 meter AUX "ANT, RF, and OSC" coil plus
the correct crystal frequency to listen to 17 Meters. The R599D manual
shows the ANT, RF, and OSC coil part numbers plus the crystal frequency
to listen to 15Mhz WWV in the aux position. I can't say with any
certainty but you may be able to modify or adjust the 15Mhz WWV coils
plus install the appropriate crystal to listen on 18 meters.

Don:

You should not have to remove boards and visually inspect for missing foils, cracked traces, addition of jumper wires etc as a matter of routine whenever you have an operational issue. However as these rigs age and pass thru many hands that may indeed need to be your standard mode of operation.

Of course any time I purchase and install a replacement board I do a very good visual and number one thing I do is install a molex plug on each molex connector one at a time and under lite and magnification I rock the plug back and forth and watch the pin solder interface for any movement. Often see the pin moving and a circumferential crack in the solder around the pin. I place the plug on to ensure the pins are all fully seated and gives me a little more leverage and simulates the action of plugging and unplugging a connector.

It is true that there are plenty of boards out there that have been butchered and cobbled attempts at repairs. I dont have them in my personal radios but seen my share.

Let us know what you find when installing the good PLL board. Hopefully display and receive will be restored. The board that had missing pads at ICs Q15 and Q16 pins are probably beyond repair and can be used to harvest parts from. The other PLL board if no serious pads or trace issues can be troubleshot and repaired if you are so inclined. Especially since you have operational radio to make comparisons.

It appears the LSB CAR Unit crystal has failed to oscillate. First try cleaning the MODE switch. If that doesn't help then check the LSB CAR Unit crystal frequency by connecting a frequency counter to the CAR Unit's "OUT" terminal. The counter should display "3393.5Khz" if the LSB CAR Unit crystal is oscillating. A separate receiver tuned to 3393.5Khz will also work.

I guess the place to start Dale is to put in the crystal and see if you can get the oscillator to take off w/o modifying the 15MHz coil.

Dale,

You will need the appropriate 17 meter AUX "ANT, RF, and OSC" coil plus the correct crystal frequency to listen to 17 Meters. The R599D manual shows the ANT, RF, and OSC coil part numbers plus the crystal frequency to listen to 15Mhz WWV in the aux position. I can't say with any certainty but you may be able to modify or adjust the 15Mhz WWV coils plus install the appropriate crystal to listen on 18 meters.

No I would not bother with the relays. I would start with the schematic and follow the path. Your symptom does not seem possible to lose audio like that although I am sure that is what you are noticing. Audio is normally produced after the receive stages and signals are sent to the audio stage. In other words, it is common to all signals except maybe a SWITCH path. So dig out your schematic and check your audio path in the mode giving you trouble and see if it goes through a switch. I would not just go messing with the relays without knowing if they are even involved. Use some sort of signal tracer or a small amplifier with a probe to find the faulty path. If you are seeing signals and not hearing audio, my guess would be a mode switch especially since you can see signals and the other modes work. Radio shack sells a small porcelain burnishing tool. This may work for renewing the contacts or put some deox-it on them also available at Radio shack with a needle dropper bottle. Brad KB2CHY

Yes you are right,there is no output for LSB
I got 3.394 for tune and same for CW
USB is 3.396 and nil for LSB
As there is three crystals which one would it be

73
Don/Ve2ud

I do have a parts TS 520,as it should be the same

The crystals have their frequencies stamped on them. The LSB crystal is identified by "3393.5" stamped on the crystal case and the PC board silk screen label is "X3".

The CAR Unit signal, in receive, is the "BFO" signal that is applied to the GENERATOR Unit's BD where it mixes with the IF Unit's signal, resulting in recovered audio at the BD's output that is then applied to the Audio amp. Loss of the CAR Unit's "BFO" signal in LSB results in no output from the BD which results in no audio applied to the AF Unit's audio amp, hence nothing hear in LSB. I don't know if you realized it or not but you also lost LSB transmit. USB and CW plus TUNE will work fine but LSB transmit will be zero.

43456. TS-830s RF board diodes

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-19 13:54:33 UTC

Group,

I actually have two of these radios, S/N 2041XXX and 3120XXX. I have spent most of my time using the newer one as it seems to work ok (over 90 watts out on 10 meters). The older one has the YK-88C and YG-455C filters so it might turn out to be the better radio. Hopefully I can learn from working on it. The older one is the one with some issues. Most obvious issue to me is low power out across all bands (maybe 80 watts). There are likely more problems that I will see after using it more. I noticed there is a group of diodes near the nine pin connector at the front of the RF board top view (I think D4 through D10), that most if not all of them are damaged (difficult to see). I have the service manual but I am having trouble identifying the diodes in the parts list. Assuming I can find new diodes and assuming I can get the RF board out, cleaned, lubed and diodes replaced, are their other components related to this diode problem that in your experience might need my attention? Root cause?
I am in the process of gathering the tools I need to properly troubleshoot this radio. I have a SM-220 scope which I need to fabricate an RF probe for. If the 220 is not up to the task I have access to a Tektronix TDS3054 scope which I am not yet familiar with how to use. I have a Fluke 744 meter as well. I am using a dummy load made from Ken's (K4EAA) design and calculating my output power from it. Typical for me, I am jumping into this hobby with both feet. I am familiar with basic electrical troubleshooting but radio, RF specifically, is a new challenge for me. I am not expecting to "get it" all at once. I plan to browse past posts for relative info creating extensive notes and use my second radio as a test bed for my education. This message board is an incredibly valuable resource and I am fortunate to be a part of it.

Don,

Replace the suspected bad X3 in your 520 with X3 from your 520 parts radio, that should fix your problem. When the replacement is complete, perform the 520's CAR Unit adjustment in the 520 service manual.

Ralph,

  The diodes on the RF board...D-4, D-5, D-6 by connector 1 are for enabling the WARC bands. D-4 is for 10Mhz, D-5 is for 18Mhz, and
D--6 is for 24.5Mhz. It sounds like someone just broke them...instead of clipping the small blue wire from Connector 6 Pin1on the RF board to Connector 6
Pin4 on the AF unit. This is easily done if you get access to the bottom of the rig.
I'll have to look more to see what the other possibly damaged diodes do.

 Low power may be caused by numerous things, as you may be aware,
Removal of the RF board is not difficult. You will need a long 1.5mm "allen wrench" to loosen
the set screws that hold the band switch shaft to the band switch in the final cage. DO THIS WITH POWER OFF
and RIG UNPLUGGED. Make absolutely sure that there is NO high voltage in there..or you'll get a BIG surprise
..as in SK. Proper orientation of the shaft and other parts essential for removal and installation. I can give you more
about that later..if needed

  Look on Pg 12 of your service manual...it shows an XRAY view of the RF board

It sounds like you are talking about the bandswitching diodes. How can you tell my looking at them that they are bad? Do you see physical damage to them? This would be very unusual and I would also want to determine the root cause.

These diodes provide bandswitch position information to the PLL board diode matrix that selects corresponding VCO oscillator and Band Pass Filters.

They also key the automatic Q1 RF amp output signal shunt when rig is in 10 meters position so that full receiver RF gain from RF amp Q1 is provided. In 160 thru 15 meters some of Q1 RF amp output signal is shunted to ground to prevent IMD and strong signal blocking. Diode D3 controls the capacitive voltage dividers that determine whether the receiver front end has full signal or reduced signal at input of RIF Mixer. A clever circuit.

All of these functions are fed from 9vdc and the diodes forward current is low. Very unusual for these diodes to be damaged from normal switching action unless somehow got high voltage on the 9vdc bus and then would think almost anything fed by the regulated 9vdc from series pass regulator could have incurred damage.

Will be hard to find original 1S1555 diodes. Since they dont actually switch any tuned circuits should be OK to sub with 1N4148 fast switchers. They are actually special bandswitch diodes with very low forward resistance so they do not D-"Q" any tuning circuits. Commonly found in VHF tuned circuit switching. I dont see why Kenwood speced them for this application?

You do not typically need a RF probe for your scope. Not much need to demodulate any signals. I think the band width of the SM-220 is very low as a bench scope. OK for audio and power supply work. You would be better off getting a VTVM for use with your RF probe. Even though your Fluke has a bar graph. Far easier to use analog meter for any peaking or nulling adjustments.

Very good Joe. The TOF diodes may have been broken during the cutting action. I forgot about that as cant imagine why anyone would do this as opposed to the simple task of cutting blue wire. No reason to replace the TOF diodes but if they broke others then will need to replace them. Much more likely the Root Cause than any high voltage on the 9vdc bus. Good work.

I forgot about the TOF (Transmit OFF Warc and 10 mhz Diodes). Joe set me straight about that.

The bandswitch info is just the 9vdc being switched by the contacts on the S1-1 deck and being routed to the Diode matrix on the PLL board. No diodes involved on RF board for this function.

The remaining diodes control D3 RF amp output signal shunt so that 1st Mixer gets full RF signal level on 10 meters where signals at the antenna will be much lower level than the low band signals especially 160 and 80. On the low bands some of Q1 RF Amp output is shunted to ground to improve strong signal and 2 signal performance.

I failed to look at the schematic and was talking from memory. Sorry about that.

Terry,

After 3 1/2 Hrs. I can confirm success. I replaced the PLL board with my known good board and the display came on and went right back off. Imagine my disappointment. So I started tracing and checking voltages. Everything was just as good as it was with the other PLL board. I checked every wire in the rig for cracked or shorted areas or pinched. Could find nothing that even looked suspicious. But I noticed that the VCO coax was very difficult to plug into the PLL board and I really had to work at it. I removed the coax completely and checked continuity. It was fine. But, not satisfied with the fit in the plug I reached into my wire junk box and pulled another out. It checked OK so I plugged it in both ends and reassembled everything. I mashed the switch and the display came on bright, flickered and dimmed out again. I removed the coax again and checked both ends. I removed some of the bumps on the pins and pressed the coax back into the plugs and twisted them a little bit to make sure they were seated. Turned on the power and the rig has been running for the last hour with good receive on all bands that had signals. Now I suspect the other board will work as well. I will work on it tomorrow. Thanks for your help, I know more about the PLL board now than I did a few days ago and have some good notes for the file.

Joe/Terry,

Thanks for the prompt reply. Yes, the diodes look to have been broken intentionally rather than having been burned. I'm guessing someone chose this method over removing the bottom cover and cutting the blue wire. Quick and dirty (lazy). I'll leave the RF board alone for now. After I find a VTVM I'll perform some more checks to determine my low power issue. I'll keep you posted (pun intended).

Ralph:

I dont remember the details of your low RF output. Low on all bands or just one or more bands? One or more is commonly due to bad bandswitch contacts.

I think you said you had a Tek O-scope. If so you dont have to wait until you get an RF probe and VTVM to troubleshoot low RF output. Look at the TX Level Diagram in your service manual and you will see the RF levels listed in RMS. These were taken with a RF Millivolt meter.

You can use the O-scope to measure these levels. Your scope will display Peak to Peak RF voltages. Just divide by 2.828 to get the RMS levels to compare to what you see on the TX Level Diagram.

For example starting with the TIF signal level at the IF board. You will see that TX Level Diagram shows 12.4mv rms. So with your O-scope should measure approx 12.4mv x 2.828 = 35mv volts P-P.

The RF output of the Transmit Mixer at TP-4 on RF board should be approx 2rms volts or 2 x 2.828 = 5.7v P-P.

Load the rig into dummy load in CW mode on 14.200 mhz to max rf output you can get without exceeding plate dissipation. Turn off SG switch. Leave heaters on. Now can measure RF drive levels from the TIF amp to the control grids of the 6146 finals. Flip to send to make your measurements with your O-scope. Depending on the input capacitance of your scope probe you may have to peak the Drive control when probe tip is touching the test point to maximize your reading.

Where you find the RF drive low is where you then focus your troubleshooting.

Don:

Glad you got it working, but having a bad VCO cable or connector cannot be the cause of having no Display when you installed the first spare board.

The VCO signal is an output from the PLL and has nothing to do with the Display. The VCO is the LO (local oscillator) for the TX and RX Mixers on the RF board. No VCO or low VCO signal and you will have no RX and TX but the display will be fine.

So I do not understand why the first spare board you installed did not result in an illuminated display? You can unplug your VCO output cable from your PLL board and your display will remain illuminated and will change frequency up and down as you rotate the VFO knob.

When you installed this first spare board and had no display the problem had to be due to not having VFO signal input to the PLL.
Plugging and unplugging the VFO Molex connector should have wiped the pins.

If the display blanks again suggest you confirm good 9vdc at External VFO connector on rear panel and re-clean the mini-Din switch. I use a spare Din plug and De-oxit it and plug and unplug the spare plug multiple times to exercise the switch.

If you said that I am sorry as I must have missed it. It seemed like you focused on the VCO cable connector which of course was the cause of no RX but not the root cause for display problem.

Terry,

I am sorry but I completely omitted the problem with the counter board. In my haste to report, I typed faster than my brain was working. The first time the display faded out on the new PLL board I took it out and examined the foil side. Found damaged traces under Q6 and Q14. So, I put in a spare known good counter board and it lit up but still no receive. That is when I went thru wire checking and onto the VCO coax. I was typing from my notes and just skipped over a few lines. Dang it! Anyway I am looking at the faulty counter board now and it appears to have the same type of trace damage. Not burned but completely missing with bare pins showing. I presume someone tried to repair and lifted the trace with to much lead in their pencil. Don't know if I can repair or if there is any damage to Q6 or Q14. Someone tried a repair but hacked it pretty good.
They bent the pins over and tried to reattach to remaining trace. May or may not be able to fix. That should clear this mess up for us and get us back on the same page. Again I apologize for the omission.
By the way, I did mention the 9v at the DIN plug and it was good but I cleaned and exercised anyway just to be sure it was stable. Have good 200+ mV VFO signal. All Receive is working fine. Now I will concentrate on the TX side. Thanks for helping me save this rig. It is in to good of shape to go to parts. Someone will enjoy it.

Hi Mike

I replaced the crystal with the one from the parts radio.Bingo it worked.
I decided to check the crstal with my crystal tester and it showed it
was good.
I then put it back in and it worked fine.
As i did not want it to act up again down the road i put the parts
radio crystal back in
Maybe i should have just reheat the pins first?
Don't think is very common for a crystal to fail unless another
component or a voltage spike would take it out.

The bottom line is that i saved hundreds of dollars with your help

Don,

  Look at the service manual, Pg 13, Section 3-18. The "S" meter adjustments are on the IF board(X48-1060-00) which is on the left side of the VFO,
on the top side of the chassis...they are VR-1 and VR-2

Don:

No reason to be sorry. I wasnt scolding you. Just wanted to make sure you did not think fixing VCO cable connector would cure the display problem.

Well very odd to have two PLL boards like this. I think you are correct someone overheated and lifted the involved IC lead pads. I dont think there would be enough lead length to bend IC leads over to bridge the gap and resolder.

You might take a look at some sockets to see if they have longer pin length and perhaps could get a small gauge jumper wire from its pins to the foil trace? Sockets would also help at any location where you see this damage as would allow you to swap out chips easily.

Best IC unsoldering tool I have ever used is a Hakko 808 but pricey for just casual user. With extra tips just over $200. In matter of seconds the IC usually will literally fall off the board.

You are making good progress. While we need parts rigs for restoring these treasures I am with you it is best if can first make an effort to fix and keep them on the air. Plus cant beat the experience you gain.

Take Care
Terry K9TW

> I am sorry but I completely omitted the problem with the counter board. In my haste to report, I typed faster than my brain was working. The first time the display faded out on the new PLL board I took it out and examined the foil side. Found damaged traces under Q6 and Q14. So, I put in a spare known good counter board and it lit up but still no receive. That is when I went thru wire checking and onto the VCO coax. I was typing from my notes and just skipped over a few lines. Dang it! Anyway I am looking at the faulty counter board now and it appears to have the same type of trace damage. Not burned but completely missing with bare pins showing. I presume someone tried to repair and lifted the trace with to much lead in their pencil. Don't know if I can repair or if there is any damage to Q6 or Q14. Someone tried a repair but hacked it pretty good.
> They bent the pins over and tried to reattach to remaining trace. May or may not be able to fix. That should clear this mess up for us and get us back on the same page. Again I apologize for the omission.
> By the way, I did mention the 9v at the DIN plug and it was good but I cleaned and exercised anyway just to be sure it was stable. Have good 200+ mV VFO signal. All Receive is working fine. Now I will concentrate on the TX side. Thanks for helping me save this rig. It is in to good of shape to go to parts. Someone will enjoy it.

43474. Grounding from shack to mains ground rod

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-20 19:59:16 UTC

Topic: 43474 Message: 43474

I am setting up a room in the house for the "shack". I would like to know if an 8 gage THHN primary wire would work to join the shack ground rod to the mains ground rod (about 80 ft.). Will this be a small enough resistance to direct lightning away from the Shack if the antenna cables and radio grounds are run through a grounding panel to the shack ground rod then to the mains ground rod.
Thanks for any input, Jerry

43475. Re: Grounding from shack to mains ground rod

Jerry,

Yes that wire should be okay for a ground. Drive an 8 foot ground rod into the ground just outside of the shack. Connect that ground rod using the 8 gauge wire to the house mains ground rod. Run the wire underground and do not have "kinks, sharp bents, or large loops" at the end of the run when connecting to the main ground rod. My shack is 85 feet from the house and power is run underground in conduit. I have an 8 foot ground rod driven into the ground at the point where the power cable enters the shack. The breaker panel and neutral are connected to the ground rod. This puts the shack and the house at the same ground potential. I have an Ameritron RSC 4 coax switch mounted on another ground rod on the opposite end of the shack some 20 feet away that's connected to the shack ground using solid copper ground wire ran underground. That puts everything at the same ground potential.

I have a 120 foot tall pine tree about 20 feet from the shack. The pine tree sustained a direct hit last summer. My inverted vee is hung from one of the pine tree limbs. The lightning traveled down the tree, through the center, continued down the other side of the tree surface, blew off bark, then traveled up the limb "next to" the inverted vee balun, and "jumped 6 feet" to the balun ground strap then flowed down the coax shield and dissipated in the ground. The coax was damage only at the PL-259. The balun sustained carbon tracks on the SO-239 but no internal damage. I cut off the damaged area of the coax, about 6 inches, and put another PL-239 on the coax and it's been working fine every since. The tree sustained some damage but the tree did NOT die, it's still doing well. Nothing in the shack sustained any damage, not even from the EMP (Electro Magnetic Pulse) that occurs in every lightning strike. I suspect if I did not have the grounding system I have I would have seen some damage to equipment in the shack.

Have a pair of twins,t599d/r-599d. When following the manual to tune the transmitter ,every thing goes fine , easy 100 watt output . The manual says to tune the transmitter with the transceive/ seperate switch on the back in separate,the light is then on for the transmitter vfo. when Iam done, I push the switch back to transceive, transmitter light goes out . I then put the receiver - transceiver switch to RX and the receiver comes to life.
When I key the transmitter, receiver mutes as it should.....BUT NO output from the transmitter, on ssb. Now If I do NOT touch any thing except to slide the transceive/seperate, back to separate when I key the transmitter all is fine,full out.
These are new to me ,have had a bunch of kenwoods hybrids over the years, these are the first twins.
anyone have any suggestions as to where to start.? I rang out the transceive cable, checks fine.

Are both the receiver and the transmitter bandswitch on the same band? If not, only the receiver will work when the back switch is in transceive.

When I said no sharp bends, kinks, or loops in the ground wire, I meant throughout the entire run of the ground wire. Small smooth bends in the wire are acceptable but sharp bends or kinks are not.

You might also take some time to look at Tom Ranch, W8JI, website where he discussed grounding.

http://w8ji.com/ground_systems.htm

and lightning

http://w8ji.com/lightning.htm

I spoke to Tom when I installed the grounding in my shack last summer. I sent him pictures and text showing/discussing how the ground rods were installed and how the grounds were connected. He said my grounding system was exactly what's necessary for protection of both the shack and the house.

Mike,
Thanks for the quick and great reply...A minor problem may be I cannot easily run the wire underground as I have an 8 inch concrete slab between the shack grnd rod and the mains which goes out from the house about 18 ft. Do you think if I went around the slab underground (probably another 25-30 ft. of wire) it would still be ok?? turns out the grnd rods are on opposite ends of the house.
Thanks again, Jerry K4GEW

I would add an additional ground rod along the under ground run. I rented a "ditch witch", makes trenches much easier. Check with your local utilities, you should have them come out and verify that the area you are going to dig will not cause damage to telephone, cable TV, and power. If you cause damage to any of these utilities because you didn't call them and have them come out to mark their lines, YOU will be responsible for repairing those utility lines!! So don't forget to consider that before you dig!!

Mike, I like the ditch witch idea and I already looked at Tom's site. that's where I learned I needed to join the mains grnd rod to the other end of the house and antenna. I just can't afford the copper flashing he used, so the THHN 8 gage will have to do. Do I have to put THHN inside conduit or just bury it?
Thanks again,
Jerry K4GEW

You can bury it, no conduit required. The only reason the ground that connects my house ground rod to my shack's ground rod is because the power cable from the house was run in conduit at the start. The other ground rod thatgrounds the Ameritron RCS4 switch box on the other side of the shackto the shack ground rod is run underground without conduit. I use separate ground clamps on the shack's ground rod. This prevents the ground rod clamp's set screw connection from coming loose. I check the ground rod clamp connections on a regular basis.

Tom's website, as you have found, is a treasure chest of valuable information pertaining to grounds and lightning. As Tom sayson his website, there is no real 100% protection against lightning strike. You can only do the necessary grounding to bleed off the static build up to "help prevent" a strike from forming.Notice the phrase, "Helps prevent" a strike which does not mean "prevent strikes from hitting your antenna and/or tower".Lightning is "unpredictable" and anyone who believes they are completely protected with a grounded system is wrong. I've read where hams says they have never been hit and they say it's because of the grounding system they have. I never believe that. It's just hasn't been his time, yet. I live 350 feet from a 150 foot tall 120KV power line metal pole. Normally it gets hit at least 2 or 3 times during the summer. I've been told by my electric company that my house and surrounding yard, including my shack, is under what he referred to as "Cone of protection by the 150 foot tall pole". When I told him him that wasn't true and explained why, that the pine tree in my back yard got hit, he changed his tune rather quickly. We can only do the best we can to help prevent the build up of static charge on our antenna systemthat could easily lead to a strike. That's allwe can, nothing more.

Hi Terry
Well JD might not be one up on you
Rig started to act up again,by arching and power dropping right off.
Now when i turn it on,i only get panel lamps and fan,as the rest is dead
Could be that the transformer is kaput? as someting has shorted out

Barry,

Congratulations on a BIG step in your "ham life". I well remember the thrill when I passed my General Class exam before the FCC examiner, and that was MANY years ago.

Let us know when and where you are operating so maybe we can work you.
73,
Don, WB5HAK

3a. Re: Grounding from shack to mains ground rod
    Posted by: "Mike" w5rkl@... w5rkl
    Date: Sat Jul 20, 2013 7:45 pm ((PDT))

You can bury it, no conduit required. The only reason the ground that connects my house ground rod to my shack's ground rod is because the power cable from the house was run in conduit at the start. The other ground rod thatgrounds the Ameritron RCS4 switch box on the other side of the shackto the shack ground rod is run underground without conduit. I use separate ground clamps on the shack's ground rod. This prevents

the ground rod clamp's set screw connection from coming loose. I check the ground rod clamp connections on a regular basis.

Tom's website, as you have found, is a treasure chest of valuable information pertaining to grounds and lightning. As Tom sayson his website, there is no real 100% protection against lightning strike. You can only do the necessary grounding to bleed off the static build up to "help prevent" a strike from forming.Notice the phrase, "Helps prevent" a strike which does not mean "prevent strikes from hitting your antenna and/or tower".Lightning is "unpredictable" and anyone who believes they are completely protected with a grounded system is wrong. I've read where hams says they have never been hit and they say it's because of the grounding system they have. I never believe that. It's just hasn't been his time, yet. I live 350 feet from a 150 foot tall 120KV power line metal pole. Normally it gets hit at least 2 or 3 times during the summer. I've been told by my electric company that my house and surrounding yard, including my shack, is under what he referred to as "Cone of protection by the 150 foot tall pole". When I told him him that wasn't true and explained why, that the pine tree in my back yard got hit, he changed his tune rather quickly. We can only do the best we can to help prevent the build up of static charge on our antenna systemthat could easily lead to a strike. That's allwe can, nothing more.

43494. TS-820S Neutralization

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-21 15:24:37 UTC
From: Terry Wagoner
Topic: 43494 Message: 43494

Newer Members and New Hybrid Owners:

Recently I spent a significant amount of time and many many keystrokes to explain to a new member and new TS-820 owner what neutralization was, why you did it, what happens if you do not do it, different methods to accomplish and pros and cons of each, differences in the instruction manual and service manual, and finally the procedure how to cold neutralize using the Screen Grid switch that Kenwood provided.

I find that this person has posted the same question on Eham. He is certainly within his right to do so. Nothing wrong with doing due diligence as long as you are smart enough to separate the BS from the straight advice. Not always easy to do.

Here is my problem with multiple postings on this site, Eham, QRZ, Yahoo Amateur Repair and other forums. You can bet that you will almost always get the same typical responses as follows:

1. I dont own a Kenwood TS-820 but I do own an Acme-123 and here is how I neutralize it. WORTHLESS!

2. I owned a new Kenwood TS-820 back in the day and here is how it worked or how I loaded it or how I did it. What is wrong with this one? Couple of things. Do you want to rely on 30 year old recall? This fellow has slept since then. Did this fellow ever have the covers off? Do you think that a brand new rig might exhibit the same operational characteristics as a 30 year old radio now does? Pretty close to WORTHLESS!

3. You need to lift the screen grid leads off the 6146 finals and tape the ends over and cold neutralize. This is absolutely the worst of the three as it is flat wrong, it is BUM DOPE. Worse than WORTHLESS!

This fellow has no idea that the hybrids have a Screen Grid switch nor does he know what it does. He also has no idea the the Anodes have potential at all times and heaven forbid you mess around with lifting it. I will let you study the schematic and if you cannot figure out the function of the SG switch from that then measure the SG voltage at pins of the 6146 finals and see what voltage readings you get. It wont be Zero!

So my advice to all recently licensed members who may have bought a technically complex Kenwood Hybrid as their first rig I am glad you you bought a Hybrid and found your way to this site. I hope with time you will come to see why this is the best site to obtain accurate information on operational, routine maintenance, and repair questions.

You have people here who freely share literally years of Kenwood hybrid specific knowledge and experience with you. These people are Subject Matter Experts (SME). An SME is someone who most recently did it and did it to the prescribed standard. By the way that isnt necessarily the most senior or experienced person as sometimes they have been doing it wrong a long time or have fallen into short cuts or bad practices or bad habits.

Those of us trying to help you had no such resource coming up at our finger tips. Also, if you get bum doped on this site you have a much greater chance of someone speaking up and correcting the error.

As for me I would appreciate it if you would say in your post that you posted the very same question on Eham and was told you needed to lift the 6146 screen grid leads and tape them over. Is this correct? I could have simply hit three keys.....NO!

It is my own damn fault trying to teach.

Just making a pitch for our Forum as the best one in town.

I wouldnt take my Cadillac to the Ford dealer. You of course are free to do so.

Terry K9TW

Hi Mike,

I'm glad you qualified your previous post on lightning. You are worlds ahead of me in understanding ham radio in general, but I've done some reading on antennas and lightning and, as you stated, if you sustain a direct hit, it's unlikely that any equipment that is connected will survive. I think a big strike could just burn up a #6 wire or even a bigger one than that. Everyone can decide what's an acceptable risk for themselves. With my lot (about a half acre) and situation, I'm not looking to put up anything big for the low bands, just verticals for 10-40M, and I've about decided that most of it will be antennas that I can put up and take down or disconnect 30 feet from the house. To hook directly into the house ground would require a run of about sixty feet halfway round the house with at least that #6 wire. A lot more trouble than picking a 13 foot T vertical hinged to a two foot post up off the ground. YMMV.

Best Regards,
Roy Kersey

As a former line locator (among other chores) I can't echo loud or long enough the importance of checking BEFORE you start digging.

Check your local phone book (if you still have those) and look for "Blue Stake" or similarly named location services. Most are supported by the local utility providers (water, gas, electric, sewer, communications providers) and will do the "locate" job as a free service. Call several days to a week prior to your planned digging.

Also, once the line locations are marked, take an elevated-view color photo of your yard. That will give you a clue should you need to figure out "why is the dirt wet, all of a sudden?", and let you know which pipe is your problem. Each type of line will be color coded as to its purpose. Generally, water lines are marked with blue paint, electric power in red, communications lines in orange, sewer in green, etc. (your local marks may vary) You can also mark in advance, with white paint lines, where you are planning to dig. If your marker crew is on top of their game, they'll take extra steps to show you the routing of lines closer to your planned dig.

John/N7IQV

>
> I would add an additional ground rod along the under ground run. I rented a "ditch witch", makes trenches much easier. Check with your local utilities, you should have them come out and verify that the area you are going to dig will not cause damage to telephone, cable TV, and power. If you cause damage to any of these utilities because you didn't call them and have them come out to mark their lines, YOU will be responsible for repairing those utility lines!! So don't forget to consider that before you dig!!

I'd like to comment about the lightning problem.

I spent many years as an EE for NASA in Arizona where lightning is a major problem.

We found the best solution was to disconnect everything we wanted protected.

In the case of a ham radio set it up so you can disconnect the antenna before it enters your shack. During the lightning system keep it disconnected except when in use. In the case of a coax feedline, pull the feedline as far from the shack as possible.

If a tree in your yard takes a direct hit all bets are off. Fingers go everywhere.

One of the places I worked where lightning was a major problem was Kitt Peak National Observatory near Tucson, Az.

Date: 2013-07-21 18:37:48 UTC
From: mvgilger
Topic: 43501 Message: 43501

The Saturday's net on 40 meter had 16 stations checking in with poor band conditions. We had 4 new check-in's, KK4NXD, KU4NY, KB1ZSQ, KD4IRB

Out of all stations checking in, there was:

3 running TS-520(x)
4 running TS-530(x)
4 running TS-820(x)
1 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 9 stations checking in under ok band conditions. Out of those, there was:

2 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
2 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39

April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 30, Sunday's total = 27
July 2013, Saturday's net total = 63, Sunday's total = 33 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

I forgot to mention that quite often cracks/breaks in foil runs occurs when people think they should reheat solder connections for no reason, quite often because someone told them to. Unless there is clear evidence of a bad solder connection, do NOT reheat the connection! The foil runs on the PC boards are very thin and can crack/break when excess heat is applied. Quite often the crack/break cannot be seen, some crack/breaks occurs under the solder pad that you can't see. If you have an analog ohm meter and you suspect there's a break/crack in a foil run, using the ohm meter to test for continuity over the foil run or from a pin to a component lead. A break will show up as an "infinity" reading on the ohm meter. You may be able to inspect a suspected break in a foil run by using a high intensity light shown on the component side and look on the foil side using a magnifying glass. Not only can you find some foil breaks/cracks that way but you can also find shorts due to slivers of solder or very thin wires that lay soldered across points they should be. Don't think this happens? Think again!! It happens quite often.

I have Alpha-Delta protectors at my coax feedline entry panel mounted on a copper plate and connected at base of tower ground which is star config ground rods that are bonded to the utility neutral. I used No. 6 bare copper. Also have MOVs in my 200amp service entrance panel and have arc gaps on the phone line.

However, when I am home and a storm is brewing I disconnect my coax connectors at the feedline entry panel and I unplug my rigs from the 120vac line. Probably should remove the chassis safety ground to protect rig from ground potential rise? I think my system will work for ESD from nearby strike, but hate to rely on it for a hit on the tower. I just dont trust the protection to do what it is designed to do. As Mike said Lightning doesnt always follow the rules. I am not sure which is worse the house burning down or having to rewind a L41 transformer!

You will get many people who are in the camp of not grounding the tower. This topic evokes much heated debate.

I like to hear the experience of long time broadcast engineers. Here is an interesting article.

I forgot to mention that I dont know anyone who has measured their ground system resistance to see if they actually have a low impedance ground. Lot of different kinds of soils out there. Lighting is high frequency so need a low impedance earth connection.

I know I have not measured my ground system. It is not easy to do. National Elec Code spec is 25 ohms and IEEE is 5 ohms which is what most utilities and telecommunications companies use.

Not as simple as disconnecting lead from your ground rod and measuring resistance to earth and by the way never want to lift your neutral and place your self in series with it.

I worked for large electric utility and their Communications Dept had test sets to perform the standard "FOP" or Fall Of Potential test. Some folks call it the 3-point test. Even with proper earth measuring test gear (Biddle is popular meter and Fluke makes them as well) it is not a simple test.

Search on Ebay for earth resistance testers and you will see why not many hams own this piece of test gear and by the way do not confuse it with a hand crank megger. A megger is used to check dielectric strength of insulation and not to be used for ground rod testing.

I suppose might be able to rent a FOP test set or if you have friend who works for local electric or phone company might be able to borrow a test set.

I have thought about chemical grounds, but that is about as far as it has gone. I am on sand. If interested you can Google on them. Essentially a 2" by 10 ft copper pipe set in center of a hole dug with a power post hole auger. Surround the pipe with Bentonite clay and fill the pipe with Epsom salt and install a pipe cap on it.

Wonder if anyone is using these?

Don't know about anyone else's area, but here I have had the power company linemen (when doing other work, not as a special visit just for that purpose) test my panel ground.

We had no power for eleven days after the 8 May 2008 storms that ripped through here. (My little valley was the site of the measured 108 mph straight-line winds that roared through.) When they were in the neighbourhood resetting poles (nineteen of them on my street alone) and removing trees (too many to count but I'm STILL burning some of them for firewood five years later), I asked one of the LOCAL - not any of the out-of-area guys who had come in to assist - if they could pop the test gear on my ground rod and see if I didn't need a new one.

It's not a long process, just takes a few seconds with the right gear. He had a Fluke meter for the purpose, and said it had rarely been used, nobody bothered with checking around here.

(We're on loam and Mississippi river-bottom clay, and it's pretty much ALWAYS wet this close to the Mighty Mississip. The water table is only about 17 feet down - I know because I drove a 6-inch PVC pipe down that far and hung a pitcher pump on it, to water the garden. Last year's drought means that this year I need to drive a new one, and I'll go down to 20 feet this time. The one at 17 feet collapsed around the sand point, and had to be pulled out and back-filled. Annoying, that.)

The result of the power company test of the ground rod? 3.4 ohms. It's the original one from Great Ghu alone knows when this mausoleum was first wired and grounded. 1960-something is my guess.

3.4 even meets IEEE standard. I'll not be too worried about any of the other ones I drive, if/when I get to run up a tower. There are minor compensations for living on a flood plain in the middle of nowhere.

I thought I spelled that out in my post as Fall of Potential Test?

Google on it and you will find good explanation of how to run the test. Here is description of several test methods.

http://www.esgroundingsolutions.com/about-electrical-grounding/how-to-do-a-3-point-method-fall-of-potential-and-induced-frequency-ground-resistance-test.php

Maybe you can earn a few bucks renting it out to hams after you write up the test procedure and validate it on your ground system.

There are more modern high frequency test sets that induce a ac signal but in some circles these are thought not to be as accurate as the old 3 point or FOP test sets.

You may want to take a close look at the Biddle test set you have. They make all kinds of test sets and more commonly will find Meggers, Hi-pots, Transformer TTR sets,Phase rotation meters,Digital Milliohm test sets etc. All test sets that Electrical Maintenance and Motor shops would commonly have. I have never seen a Biddle Earth Resistance test set. Sure would be good find if you have one.

Roy and others,

Damage to your radio can still occur even if you disconnect the coax feed line, throw it out into the yard, and disconnect the radio's power cord from the wall outlet. How does this happen when the radio's not connected to anything? Simple, the damage occurs due to a lightning bolt's rising EMP Magnetic field lines of flux that occurs with every lightning bolt. EMP stands for Electro Magnetic Pulse"

The easiest way to explain it is for you to take a glass rod or long pencil and run it through a doughnut. Use gloves, the good tasting glaze is pretty sticky. The rod or pencil represents the lightning bolt and the doughnut represents the lightning bolt's rising EMP magnetic field's lines of flux, radiating outward from the lightning bolt. When a lightning bolt occurs, current flows which is what produces the bright "leg" of the bolt you see. When current flows, a magnetic field is produced that radiates outward from the bolt. If your radio is in the path of the "rising magnetic field" of the lightning bolt's EMP, then the component leads and wiring will "cut" the rising magnetic field's lines of flux resulting in a current flowing in the radio. It's this current that flows is what causes the damage to the radio.

Thunder is the rapid expansion movement of heated air surrounding the lightning bolt. As the rapidly moving heated air expands outward from the lightning bolt, sound is produce (explosion if it happens near your house) or a "rumble" if it's off in the distance.

Power transformers use magnetic fields to induce voltages in the secondary windings. Lets take a simple filament voltage power transformer that has one primary winding and one secondary winding. Applying AC voltage, 120VAC at 60Hz, to the primary winding, a magnetic field is produced. The magnetic field rises and falls at "60 times per second" (60hz) and the rising magnetic field cuts the windings of the transformer's "secondary windings" which results in an voltage to appear on the secondary windings.This is exactly how a lightning bolt's rapid rising of it's EMP magnetic field's lines of flux cause damage to radios that are not connected to anything, the leads, wiring, etc, cuts the rising magnetic filed causing current to flow where it shouldn't resulting in damage.

That should make a very effective ground. Only concern I would have is the electrical connection. I suppose if not exposed to the salt water then would not corrode. Same with the home copper pipe salt ground would have to keep connection above salt level and inspect regularly. I suspect folks who operate ham radio out of salt water vessels have some special connections to their hull ground plates?

Sorry to digress from Kenwood Hybrids but safety and rf ground is relative.

I think I am just going to assume I have done best I can with my tower ground rods and bonding to my utility neutral.

THANK YOU. I had lost that article or a link to it, some time ago after a disk crash. Never got around to looking for it again.

The advice there is meant for the big guys and commercial installations, but works for amateurs just as well. Physics doesn't play favourites.

The best (and probably the most-ignored) part of the article is the bit about bonding the coax sheath to the grounding strap or to the grounded tower structure, at the TOP of the mast/tower (right at the antennas), at the BOTTOM of the mast BEFORE any bends to horizontal, and then again at the ENTRANCE to the building.

The coax sheath/braid is grounded THREE times.

Most people do only one, at the shack entrance....

It isn't enough, not if you're serious about trying to keep the sparks out of your house. An antenna mast is a really big and attractive (pun intended of course) target for a lightning bolt. I don't think that I should be adding that much more risk to my family just for a hobby.

Taking the time and effort to properly ground things only makes sense.

Wes:

If he just checked your neutral at your meter base that is not good enough. You need to check your driven ground rods individually. To do that you have to disconnect them.

I am surprised he had a meter. Utilities arent worried so much about lightening or ESD and dont really care if your Ham station ground system is a good low ohms single point ground system. They have arrestors at your distribution transformer to address lightning.

They do however have an obligation to give you a good low ohms neutral so that you have a stiff nominal 120 vac on each side of your service under full load conditions.

They are more concerned about service entrance "neutral shift". If you have a high resistance neutral or have lost your neutral the 240vac supplied from the distribution transformer secondary to your breaker panel will not split evenly to 120vac from each hot leg to the neutral in your service panel under load. This can be a very bad thing.

You could see 180 volts to ground on one side and 60 volts to ground on the other side or many other unbalanced voltage combinations depending on what loads you have cycling on at the moment. This of course is not good for any of your 120vac appliances. Electronics and compressors will complain. If you can prove that you have lost your neutral that resulted in lost appliances you have the basis for a claim with your utility. They do not advertise this.

In old days the servicers or trouble men all carried on their trucks electric irons or ceramic cone heaters with the plugs cut off and alligator clips on the leads. This gave them a 1200 to 1500 watt dummy load. They would pull your meter and connect this dummy load from hot leg to neutral and measure the voltage. They would do that on each side of your service and if the voltage did not split evenly they knew you had a bad neutral. They would then re-do all the neutral crimps from your service entrance back to the pole.

Later someone invented a nice tester that had high wattage switchable dummy load in it and a voltmeter on front panel. You pull the KWH meter and insert this tester in its place and flip the load switch back and forth and watch the voltmeter to see how evenly the voltage splits under load. I wish I had thought of it.

Anyone can do this test with a hair dryer or space heater if they are careful in their service entrance panel. Can make a lot of fireworks in there as almost infinite current capacity. At least it will seem like it as tools can vaporize and copper splatter not good for your eyes.

Sounds like you have the standard Star ground rod configuration and it took some work to do it. I too would be worried about the corrosive affects of adding salt water around the rods.

You are correct about likely hood. I have seen colored maps of US that show likely hood of lightning strikes and places like Florida rank pretty high. Silly to spend a lot of money on good single point ground system if you live where strikes are rare.

I am going to do some research on Cell Tower grounding. With proliferation of these lower height towers with electronics mounted on them you can bet the engineers have come up with the latest in lightning protection. I suspect bonding of feedline shields and arc gaps or movs on the center conductors are a piece of it.

This group is the best resource I have, Terry, and if it wasn't for you guys I would have sold my 820 a while back because it sure is complex for a first rig. I sure like it a lot more than the Yaesu FT-757GX that I also got from my Uncle before he had to go into a nursing home.

I am sure it's me you are calling out here, and I sincerely apologize. I think I was on eHam.net one morning before I posted the question here. Like you mentioned, I have read so much in doing my due diligence so I don't bother you guys that I probably put it there just to get their feedback while I was on there.

I wish I was much nearer you guys so I could be an apprentice of yours. Then I wouldn't have to bother anybody with any questions at all. I just appreciate everybody's help so much and am sorry for any offense.

I know 20 years ago I knew absolutely nothing about IT or Graphic Design and had to start at the level I am on with ham radio now. It's now how I make a decent living, and I am proficient at it. In 20 years I hope to be at that level with ham radio, and it sure will largely be because of you guys and your help.

I just can't seem to find the answer for this, in the manual it says to peak the ALC reading with the drive control. The manual says "maximum meter deflection", does that mean full sweep or within the ALC range?

> If he just checked your neutral at your meter base that is not good

At the time that was the only ground rod in the place. It was the only one he checked.

He used one of the new Fluke meters, something like a 1.7 kHz (I looked that up, I didn't remember the frequency he said it used) signal injected right at the ground rod. It was only good for small systems, he said. They had an FOP set on one of the other trucks for big buildings.

Apparently for small systems, the readings they got using the Fluke were almost identical to the results that came from doing a full FOP nine-measurement set.

AND it was done in a very small fraction of the time it took to drive the X and Z rods and measure and maneuver around to find clear spots exactly 1-9 times the diagonal length of the ground system.

He said they had a heck of a time sometimes (in cities mostly, since that's where most of the big buildings seem to be for some odd reason <-;) finding a place to GET to earth at the required distances. Concrete everywhere.

But since I'm repeating an anecdote about the concrete, if that information is incorrect I'd appreciate knowing it. Sounds plausible, but so many things do.

I had heard about the imbalanced ground business and loading splits that weren't even, but have never run across one myself. A 60/180 volt division sounds quite the recipe for letting out some magic smoke.

"X" and "Z" rods for the test, with associated connectors and clamps.
You'll be taking nine measurements at multiple distances of the
"diagonal length" of the grounding system. It's a bit of geometry that
takes into account multiple rods, usually used for commercial
installations and also by the savvier hams....

>I have oft debated
> whether or not to soak the ground with salt, to improve the ground, but, as

Please. Don't.

The salt will spread and kill off about anything around in the way of
vegetation. Including trees. And the salt contamination will remain
for a -very- long time.

This is why ancient armies would "salt the earth" of conquered foes.
The land would be rendered more or less permanently incapable of
sustaining life (including food crops) and the vanquished enemies would
be forced to move away.

Putting down enough salt to affect your ground resistance in any
appreciable amount would likely leave you in the middle of a large
barren patch of dead land. Not to mention the salt would contaminate
the ground water which would eventually wind up in any lakes, streams,
rivers, or wells in the area. It might also get you some attention from
the EPA folks, if you do a 'good' enough job of it, for contaminating
the ground water.

This kind of thing is one of the reasons I'm dead against this
"fracking" nonsense. Toxic waste is toxic waste and it does NOT belong
in my drinking water.

(I've been to Wood River, Illinois, where, thanks to the poorly-run oil
refineries spilling so much petroleum over the years that the ground
water contains so much gasoline that it BURNS. They get their water
from a LONG way off now. ANY replies or comments to this, kindly do it
off list, please. Off-topic, I know. No more to follow here.)

Hi Mike and All:

Mike, thanks for the tutorial, but I have a science degree and know all about Maxwell's equations in principle. Your rig could also go south in a nuclear attack due to the flipping of the magnetic fields and your car wouldn't run, either. Nor any computers and you can forget data storage, too. Same true for a coronal mass ejection. No argument there.

I don't want to take your time away from answering other, more pressing questions.
My questions would be, am I better off taking the antennas down, as I described, or just having the grounding system you described? Another questions I have is, do you know anybody who's had his rig destroyed by the kind of EM fields you described? How frequent is that versus voltages coming in on an antenna line or whatever during a lightning strike? I'm sure it has happened, but how frequently compared to other varieties of lightning damage?

Best Regards,
Roy Kersey
KI4HAG

I tried sending this reply 3 times this evening and Yahoo's server didn't seem to cooperate so here is it for the 4th time.

Roy,

You're asking me a question that I can't answer. I can't say with any certainty the number of home electronic devices/radios/ham gear that have been damaged/destroyed by a lightning bolt's EMP field. No one can. I could be wrong but I don't know of any statistics that covers the percentage of damage to electronic devices, including ham gear, that occurs due to a lightning EMP field. I can only tell you experiences I have had, what I have learned over the years about lightning and the importance of grounding, and what others have told me about their experiences. My neighbor, for example, is not a ham, does not have any outside antennas, but he lost a few electronic devices due to a lighting strike that hit a pine tree just outside his house. The damage occurred by the lightning's EMP mag field. Having said that, my inverted vee hangs from a pine tree limb some 20 feet from the shack and one end runs to the chain link fence about 8 feet from the shack. Lighting hit the pine tree last summer but I didn't sustain any damage to any gear in the shack. Why did my neighbor have damage and I didn't? I can't honestly say why. I can only say that it appears the charge rapidly dissipated into the ground through the coax shield that's connected to the PL-239 that was laying on the ground. Does that mean you will have the same thing happen to you? No. I don't have a crystal ball, no one has, that can tell me or you when and/or if you or I will ever be hit. Lighting is part of nature and will continue to be long after you and I are gone. We do what we can to deal with it and if that means you disconnect the antenna feed line as it enters your house/shack and toss the feed line out into the yard and lower your antenna while the storm approaches, then do that. I've been doing that for years. I have a dual SO-239 screw type barrel connector in series with the coax feed line outside the shack. Makes disconnecting the feed line very easy. I even lower the inverted vee at times when severe storms are approaching. We have some really bad storms here at times but a that doesn't stop me from being a ham with outside antennas! It's nothing more than a slight inconvenience during a thunderstorms but I don't worry about that because I don't operate during a thunderstorm anyway.

I could be wrong but I seem to recall you said you have a vertical. I don't know if you are aware but DX Engineering sells a mounting plate that allows a vertical antenna to be lowered down on the ground when storms are approaching and when the storm passes, the vertical is raised back vertically again. See the following link for details:

http://www.dxengineering.com/search/department/antennas/product-line/dx-engineering-tilt-base-mounting-plates?autoview=SKU

In addition to installing proper grounds and if you feel better by disconnecting the antenna feed line outside the shack and tossing it out in the yard and use simple "Common Sense", those are the best things you can do.

No apology due. If I were new I would be looking at and evaluating all the resources at my disposal.

Just want all new KW hybrid owners to be aware of the kind of advice that I see routinely given on these other sites. I go there from time to time to try and help and almost always get in arguments with one or more of these fellows who think sniffing, tapping, and spraying contact cleaner fixes all.

Steve, Carl, and Sue (current KW owners or former KW owners) typically give sound advice but there are so many more that respond exactly as I stated in my 3 examples. I did not make those up.

I too wish you lived close. You would be welcome in my shack at any time.

Have fun with your TS820 rig.

OK I have heard of these test sets but not seen them in use.

I was talking about additional ground rod systems driven with most tower installations that are bonded to the utility neutral. With several ground rods in parallel not sure how you would measure the individual resistance of each rod to ground without lifting leads to measure. Perhaps the test set is measuring injected current in each leg and calculating the resistance and displaying it?

Your question is the first one I asked when I bought my first Hybrid. It is a natural question.

Kenwood finally got around to answering it in the TS830 instruction manual by stating if the indication goes outside the ALC range (black rectangular box) to adjust the Carrier control for an on-scale reading.

Unfortunately this isnt necessary, but was the easiest thing for them to say rather than go into lengthy discussion of what is being displayed.

The correct answer is to just adjust the Car Level pot to keep meter off the peg (full far right hand edge of the meter scale). What you are seeing is a relative indication and the ALC rectangular black box on the meter scale means nothing at this time. That box only means something when you are modulating the rig in SSB mode. Just bring up the Car Level pot to give yourself a decent level to peak with. That can be at 1200 or 2/3 of full scale or 3/4 of full scale.

If you are concerned then just use the max of the ALC scribed black box. Nothing wrong with this as long as you understand you cannot exceed control grid dissipation.

This topic will result in lots of disagreement. I see videos on You Tube where the presenter places lots of attention on making sure that while peaking the Drive Control you do not exceed the maximum ALC indication or that you keep it in the center of the range or after loading to 100 watts output go back and re-peak and make sure in ALC range. I have read the experts on QRZ cautioning KW owners about exceeding the 8ma max grid current level. All of this is nonsense.

In the 50s/60s we all had Class C grid leak bias CW transmitters with a single or double 6146 final. These rigs had a Grid Current meter position. When we loaded those rigs we had Drive control that was adjusting a tuned circuit to resonance and maximum rf voltage. Some also had a Drive Level control which was typically adjusting the Screen grid voltage of the Driver tube. All the manuals quite appropriately cautioned us to make sure when peaking the Drive not to exceed 3ma or 4ma if one tube and 8ma of 2 tubes. A 6146 tube has a maximum control grid dissipation rating same as the plate does and if you exceed that level you can quickly destroy the tube. The manual also directed that after loading to go back and re-peak the Grid current as it commonly had fallen off.

I think that is why people teach that you must keep ALC inside the black box. I think they are afraid you can exceed the control grid dissipation and damage your finals. THIS IS WRONG.

Your rig is not a Class C CW rig. It is a Class AB1 transmitter. It takes no grid current to drive this rig. All you need on the control grids of your finals is a RF voltage that is swinging the grid. When you peak the Drive control that is what you are doing you are maximizing the voltage swing by adjusting a tuned circuit in the Driver tube Plate circuit to resonance. In actual practice it does take some power as you are supplying the grid circuit losses primarily the charge and discharge at an rf rate the internal electrode

capacitance of the tube. The grid impedance varies from infinity when there is no grid current to approx 500 to 1000 ohms when there is grid current.

OK what is the grid current level? The instant the control grid goes positive with respect to the cathode (this happens when the RF drive voltage exceeds the DC operating bias voltage) and there is a hint of grid current the ALC amplifier transistor turns on and reduces the dc control voltage to the TIF amplifier. The TIF amp supplies the RF drive to your Transmit Mixer. Your ALC meter is measuring this DC control voltage. The ALC amp transistor acts like a variable resistor and when it turns on it pulls the ALC bus voltage down. This is what your ALC meter is displaying. The lower the ALC bus voltage goes the higher the meter indication.

So indirectly your meter is measuring control grid current. With the Car level set for an mid ALC indication this current will be approx 35 ua. With it at far end of black box it will be approx 40 ua. The maximum current is approx 45ua. Note this is micro amperes and not 4ma or 8ma or any such level that could hurt your finals. These are not values I am guessing at. I have measured them on all Hybrids. See Ken K4EAA site for his discussion of the ALC servo system. Go to the TS520S manual page 29 and read the ALC circuit description and it states ALC voltage will begin to be reduced when approx 30ua of grid current begins to flow.

As to going back and rechecking and re-peaking your ALC level after loading as so many do where in the manual does it say to do this? In fact in the TS520 manual it does state at the end of the loading instructions that there may be no ALC indication with 200 ma of plate current. This is because the rigs use RF negative feedback and at this level of plate current there is no ua grid current flowing as the RF drive voltage has been reduced to just below the dc operating bias voltage on the grids. If the grid is not positive with respect to the cathode there can be no grid current.

So short answer is the ALC meter in Tune mode is just a relative indication and no concern about exceeding maximum 6146 grid current. If you want to adjust the Car Level to keep the indication in the black ALC range that is fine but not necessary. Any time you cant get a indication simply increase the Car pot level and any time it goes off full scale simply decrease it.

A good TS520 Driver stage should be able to get full scale (FSD) ALC indication on all bands with exception of on 10 meters. Perhaps 2/3 to 3/4 is the norm there.

Sorry so long. Much confusion and myths and wrong info on this subject.

Roy:

Maxwells equations, displacement current, couloumb field have all bewildered me for years trying to figure out how a dipole actually radiates. Have speaking acquaintance, but would be fibbing if I would tell you I really understand the science. A topic better addressed off the list. Warn you no hope for me!

I think we can all debate or quibble about Lightning EMP and different pulse level designators and ESD or other terms. In my mind regardless what we call it the result has to do with the distance from the strike and how much wire is in the air in the pulse magnetic field path. If close enough ie within feet of your electronics then the magnetic field could be intense enough to cause you computer monitor screen colors to distort or worse. Same as bringing a permanent magnet or deguassing coil close to the monitor.

I suppose if close enough the pulse magnetic field could damage the RF amp mosfet in a Hybrid with no rig connections to the outside world at all. I think we are talking nuclear bomb here and not Lightning EMP to get that level of magnetic field.

I think for a KW hybrid there are at least four paths outside of a direct hit and whether we can attribute it to EMP or ESD is academic:

1. Induced in your wire antennas and feed lines as they act as secondary winding of transformer. (As Mike explained)

2. Induced in your 120vac lines as the power line primary and secondary conductors in the air act as a secondary winding of a transformer.

3. Induced in your phone lines and cable tv lines in the air as they act as secondary winding of a transformer.

4. Thru your chassis safety ground due to ground potential rise in the power line neutral. (not induced from pulse flux field)

So only 100% protection for our Kenwood Hybrids (assuming house doesnt burn to ground) is to remove the antenna feed line, unplug it from 120vac recept, and lift the safety neutral off the chassis. Ok.. place in box and put in closet!

Not many of us are going to do any or all. I am one of the lucky ones who have never had a near by strike or any damage in over 50 years.

43531. TS520SE IALC problem back to haunt me!

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-22 14:59:32 UTC
From: adrian.langford@ymail.com
Topic: 43531 Message: 43531

Prior to today I had been able to align my 520SE (with Terry's invaluable help!) so that I had full scale ALC on all bands. Before I had no ALC on 10m at all.

Turning on the rig today the ALC was much lower than normal when I tuned up. Where I could get FSD on 7MHz with carrier control around 3 and drive peaked, I now had to wind the carrier full clockwise and only get about 3/4 full scale. Checking each band I found I was getting no ALC on 28, and progressively higher peaked ALC going down bands to 3.5MHz (7 and 3.5 about same).

This had happened once before and when I checked idle plate current it was about 40mA not 60mA. After setting to 60mA the ALC was fine.

So I checked idle current and it was around 45mA. Thinking this would be bound to fix the ALC I increased to 60mA, but I still had same low ALC! Maybe it was just coincidence that last time I had to readjust idle current, the ALC was its old healthy self?

So what could cause a sudden decrease in ALC, and complete loss of it on 10m where it was fine before post-alignment? What's obvious place to look? Could it just be finals have given up? Any reason why the idle current has dropped since last adjusted to 60mA just a few weeks ago when I last saw this problem?

Thanks for your advice.

Adrian:

After you adjust the resting plate current to 60ma does it stay there for some time or does it drift pretty quickly? Idle current is a function of cathode emission, control grid operating dc bias voltage, and screen grid voltage. If finals have lots of age emission can be a problem. Otherwise bias voltage and screen grid voltage must be to spec and stable.

If you feel comfortable I would measure the grid bias voltage at the final board on the control grid pin of the tube socket. It is not often that the -C supply floats around, however if the bias voltage pot is dirty it can cause resting plate current to change. If you havent cleaned and exercised this pot it is good idea to do so. Easy to remove the three screws that hold the plate to side of rig to get access to pot to apply the Deoxit and canned air. Try to set it back close to original position so you dont have insufficient bias voltage and the finals run away and be destroyed when you first key rig to adjust to 60ma.

As you know ALC indication is a function of RF drive voltage and dc bias offset at the control grids of your 6146 finals. Assuming that DC bias voltage is set properly then need to measure the RF drive voltage. If RF drive voltage is low suggest you try a new 12By7A Driver tube as a first step.

Topic: 43531 Message: 43535

Hi Terry

Thanks for such a fast reply!

The idle current stayed at 60mA for the 20 mins or so between me setting it believing it would be the fix, and turning rig off for the day after checking all the bands and scratching my head.

I had to leave home then for work and won't be back till weekend. I will then get rig in bench and do all the grid voltage checks you talked me through last time using my notes from then. The 12BY7A driver is a new one.

Will also clean bias pot first as you suggested, though the idle current varied smoothly as I rotated pot. I will note current position before cycling the wiper.

I left out one data point which may be relevant. I had not had any QSOs on 15m (conditions poor for it since obtaining rig) but yesterday tried a number of times to answer a QRZ without being heard in a pile up. I was putting out usual 100w, but when I checked SWR (I'm using OCD dipole 80-10) I found I had an SWR of over 5:1 (in lower bands this antenna around 1.5:1). I wonder if the reverse power damaged the finals? Problem is I can't remember if I had normal ALC after finding the problem on 15m. The dipole does take a curious path to fit my yard...

Anyway thanks as ever for great advice. Will report back to this group at weekend.

Adrian:

In case you have forgotten to determine how much RF drive voltage level you need here is how you do that.

1. Measure the operating dc bias voltage at the 6146 control grids
2. Assume it is -55 vdc
3. -55/1.414 = 38.89 rms rf volts.
4. 39 x 1.414 = +55 peak RF volts so you can see that on the peak of the positive going half of the RF drive envelope with -55vdc bias the grid never goes positive relative to the cathode. No grid current means no ALC action.
4. So you need greater than 39 rms rf volts to have any hint of ALC indication. Any less than this and zero ALC indication
5. For maximum ALC indication at 100 watts into dummy load you will need approx 46 rms rf volts for maximum ALC indication.
6. 46 x 1.414 = 65 peak rf volts.
7. At the peak of the positive going half of the RF drive level the grid is approx +10 volts with respect to the cathode. Ua grid current flows from cathode to grid and to -C return. ALC amp transistor is turned on. ALC bus voltage is pulled down. ALC meter is driven up scale.

Summary:
A. Must have more than 39rms rf volts to get ALC indication off zero
B. Must have approx 46rms rf volts for full scale ALC indication at 100 watts into 50ohm dummy load.

It is not possible for "high" SWR to overheat the final tubes as long as you can re-tune the Pi-network for Ip within maximum disspation rating of the tubes. Overheating would come from not tuning the network to resonance and running with higher than maximum plate current.

It is possible for high SWR to cause arc over of the Plate Load capacitor and/or cause heating in the Tank coil due to higher circ current. Arc over would be the more common problem.

As long as you can adjust your Pi-Network controls to load into the mismatch that is being presented should not hurt the load capacitor or the tank coil.

5/1 SWR is getting at the extreme limits of your Pi-network to affect a match.

Do all your testing into a 50 ohm dummy load.

I had not had any QSOs on 15m (conditions poor for it since obtaining rig) but yesterday tried a number of times to answer a QRZ without being heard in a pile up. I was putting out usual 100w, but when I checked SWR (I'm using OCD dipole 80-10) I found I had an SWR of over 5:1 (in lower bands this antenna around 1.5:1). I wonder if the reverse power damaged the finals? Problem is I can't remember if I had normal ALC after finding the problem on 15m. The dipole does take a curious path to fit my yard...

Do you have another "new" Driver tube? If so try it. Or perform Driver stage test in CW mode with SG switch off as I have described previously.

43539. TS-830s Remote Connector

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-22 20:10:26 UTC
From: ralph_ts_830s
Topic: 43539 Message: 43539

Group,

I have had no success locating the 7 pin remote connector for my TS-830 until now. I recently purchased this cable to use with an amp http://www.ebay.com/itm/360575254804?ssPageName=STRK:MEWNX:IT&_trksid=p3984.m1439.l2649#ht_1299wt_1161
I asked the seller if he would sell me the connectors and/or make up cables for me. He is willing to make cables. I am going to ask him to make two cable 25"'s using a 7 conductor (8 with the shield) cable and leave the other end unfinished so I can adapt it for future uses. In particular, I am planning on using one to interface with a foot-switch. He asked $29.00 and change for the amp cable so I expect the cables he makes for me to be the same or close. This might be pricey but he's got it and I need it. Anybody have a source for these connectors? Looking at the operating manual it looks like I will use pins 2 and 3 for the foot-switch?
Pinout is as follows:
1= Record out (audio)
2= Relay common terminal (not grounded)
3= PTT line
4= Normally open (relay contact)
5= Normally closed (relay contact)
6= ALC input (threshold level approx. 6V) Manual states -6V (up to 6?)
7= Open (no connection)

Arrgghh! I found the amp cable before I found this group :-(
Looking more closely at figure 5-4 page 25 of the Instruction Manual, pin #2 would not be correct for a PTT foot-switch. In addition to pin #3, what pin should I use to complete the PTT circuit for my foot-switch?

Thanks Terry - I will print this out along with original thread when I first got the 520SE (at that time aligning the Drive coils Restored ALC to health on all bands including 10m) and work through the grid voltage measurements.

I should be able to try the original driver tube (gave to my son so he'd have momento of thermionics!) so will try that and measure the RF drive with the old and new tube.

Thanks again for your patient help

> >
> > I left out one data point which may be relevant. I had not had any QSOs on 15m (conditions poor for it since obtaining rig) but yesterday tried a number of times to answer a QRZ without being heard in a pile up. I was putting out usual 100w, but when I checked SWR (I'm using OCD dipole 80-10) I found I had an SWR of over 5:1 (in lower bands this antenna around 1.5:1). I wonder if the reverse power damaged the finals? Problem is I can't remember if I had normal ALC after finding the problem on 15m. The dipole does take a curious path to fit my yard...

Idle current is a function of cathode emission, control grid operating dc bias voltage, and screen grid voltage. If finals have lots of age emission can be a problem. Otherwise bias voltage and screen grid voltage must be to spec and stable.
> > >
> > > If you feel comfortable I would measure the grid bias voltage at the final board on the control grid pin of the tube socket. It is not often that the -C supply floats around, however if the bias voltage pot is dirty it can cause resting plate current to change. If you havent cleaned and exercised this pot it is good idea to do so. Easy to remove the three screws that hold the plate to side of rig to get access to pot to apply the Deoxit and canned air. Try to set it back close to original position so you dont have insufficient bias voltage and the finals run away and be destroyed when you first key rig to adjust to 60ma.
> > >
> > > As you know ALC indication is a function of RF drive voltage and dc bias offset at the control grids of your 6146 finals. Assuming that DC bias voltage is set properly then need to measure the RF drive voltage. If RF drive voltage is low suggest you try a new 12By7A Driver tube as a first step.

Subject: [TS-520_820_530_830] TS-520S Drive Tuning

I just can't seem to find the answer for this, in the manual it says to peak the ALC reading with the drive control. The manual says "maximum meter deflection", does that mean full sweep or within the ALC range?

Hi Gordon Some days back I posted about my 820S with a intermittent display digit i.e 7.150 reads 9.150 on any other band also.

After working on the counter boards, for some days the display worked fine, however it still briefly will change to 9 on the second digit and
has no effect on the TX or RX functions.

You mentioned the bandswitch as a possible culprit. What specific bandswitch section controls the MHz portion of the display?? I have the 820 Service Manual.

Many Thanks & 73

Hi Bill,
It has been years since I worked on an 820. Two things come to mind. One is the contacts for the wafers on the Band switch . I think Wafer #3 is the one you want to look at. The other, which is a very common but less mentioned problem is the little metal spring terminals inside the white connectors. These terminals Break over time and then no longer make contact with the Pin they slide over. I have solved more troubles then I care to remember by replacing these terminals. It is a pain in the butt because the only way to check them is to release each one from the white plastic connector and slide it out to look at it. Very time consuming. It is the main reason I stopped working on the TS-820 radios. I am confident, now that I think about it, that you will find your fix by locating the broken contacts on your radio.

Topic: 43550 Message: 43550

First thanks to all the great hams on this site for all the great info I've received. My question today is, is the tune up procedure the same for the 820s, 530s, 830s all the same or are there differences? Also when I tune my 820 and I get to the step in the manual where the mode switch is in cw position meter set to rf Ikey to peak the load and dip the plate as I turn the plate control it will just continue to dip until the control is way out of the band I'm intending to tune for. I hope I explained that correctly.What am I doing wrong? Also on a 530s when tuning for 20 meters the send switch does not operate. It works just fine on all other bands but does nothing on 20. Thanks again and I hope someone has an answer and not a flame. I've never seen anyone do that on this site that's why I'm here. I've asked a few questions on qrz and it seems some folks would rather bite you than help you. So Peace be with you all and thank you again. 73 Richard KM5WX

From: Terry Wagoner
Topic: 43520 Message: 43552

This is wrong and bad advice to give to new folks trying to learn how to load their rigs.

Hard to adjust the Driver Tube plate tank circuit to resonance if you are bringing the Car Level up to full scale meter deflection. How do you then see the "PEAK" ???

Are you peaking the ALC reading with the Drive control and then bringing up the Car Pot until you set the meter indication at FSD? If so, this is meaningless. From about 1200 on ALC meter indication there is no increase in RF drive voltage at the 6146 control grids.

You can see this if you operate CW mode. Bring up the Car Level and peak the Drive control for 1200 indication on the meter scale. You should see approx 100 watts output. While key down open the Car Level pot up to run the ALC indication from 1200 to FSD. You will not get anymore RF output. If you do not have an external wattmeter then use the rigs RF detector position.

You need to "PEAK" the ALC indication and to do that you need the meter off the peg to see the peak. You are not looking for a particular ALC indication meter level only a PEAK.

Set the Car Level so at a minimum you have ALC indication at the far right end of the printed ALC box on the meter face and then adjust the Drive Control for a Peak. It is just that simple. As I said in my previous explanation you can use 2/3 or 3/4 meter scale and there is no worry of exceeding the 6146 control grid dissipation as so many seem to be concerned about.

What you are doing is adjusting the Driver tube plate tank circuit to resonance. At resonance you will have maximum impedance in the tank. At maximum tank impedance you will have maximum RF drive voltage.

With the ALC indication "PEAKED" at far right end of printed ALC scale or greater you will have approx 46rms rf volts on the control grids. You will get no more rf drive voltage at control grids by trying to Peak the ALC indication at meter FSD.

The goal of this loading/tuning step is to have the Maximum RF drive voltage on the 6146 control grids. Kenwood didnt provide a control grid rf voltmeter to indicate when you are there. Since there is no dc grid current they did not provide a dc grid current meter. So how do you know when you have maximum RF drive voltage at the control grids? Kenwood does it by measuring the ALC bus voltage. A "Peak" in the ALC indication tells you that you have the Driver tube plate tank circuit tuned to resonance.

For you new folks this is a no brainer.

43553. Re: hybrid tune up procedure

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-23 12:13:39 UTC
From: Terry Wagoner
Topic: 43550 Message: 43553

At this step with the meter in RF position you should be adjusting the Plate Tune and Plate Load controls for a maximum indication on the panel meter and not a DIP. If you have a low reading adjust the RF sensitivity pot for approx 2/3 to 3/4 deflection on the meter so you have something to work with.

As I said you are not looking for a dip in the RF meter indication. With the meter in RF position you are sampling the rf voltage at your SO-239 connector. Maximum rf voltage = maximum watts output.

The meter does not tell you if you have normal RF output into your dummy load (approx 100 watts at normal Ip). It is just a relative power indication.

This is one of the reasons I recommend newly licensed and new hybrid owner consider buying a wattmeter. Through no fault of your own the understanding of a Tank circuit and what you are doing when you adjust the Plate Tune and Plate Load controls isnt there yet. It will come with time if you have the aptitude and interest to learn. If you feel flamed too bad.

At this point you need a SWR meter to trim your dipoles so why not spend couple extra dollars and get a directional wattmeter that serves both purposes. So much easier to just adjust the Plate Tune and Plate load controls for approx 100 watts output. You can then leave your panel meter in the IP position so that you can simultaneously see that you are not exceeding max IP. Also the meter ballistics of most wattmeters is much better than your panel meter. This means much more sensitive. Making it easier to see a peak on the wattmeter than you can see the dip in IP. Also dip in IP doesnt always correlate to max rf output power. Wont spend time explaining why at this point.

Perhaps someone else will address the 20 meter issue for you.

I worked the Czech Republic, France and Poland last night on the 820 after researching several different dipoles, and with $12 of 14 gauge wire. 44' for each leg and maybe 25' or so for feedline allowed me to throw it up over the house and spread it out pretty well over my front and back yard, and it's up about 14' or so.

That's my first homebrew antenna, and it's not perfect - SWR was a little high, so I'm going to keep working with it - but the very first contact was the Czech Republic. He gave me a 5-7, and I'd have to give him no better than that... but I was very pleased to have done this well last night.

I think my 820 is in better shape at 30+ years old than I was.

Hi Barry,
Congratulations-good work! I think dipoles are great-you can experiment with them, put them into different configurations, and they don't cost much. Now you can try to get your dipole up a little higher and your SWR may go down, plus you can trim the ends. You can also configure it as an inverted Vee if that would help get it up higher. Good work and keep it up!

Don,

What hybrid are you referring to? When asking about problems with your hybrids you must provide the model of hybrid you are referring to.

Are you saying that you measured the AC voltage on the 12VAC winding and it's zero?

Did you check ALL of the Rectifier Unit voltages before thinking the Rectifier Unit is bad?

Did you check to see if the driver and both final tube filaments are lit (Heater switch turned ON)

If the driver and both final tube filaments are lit and the dial lamps are illuminating then the 12VAC winding is fine.

The fan runs off of the 100VAC winding of the power transformer and if the fan is running then that winding is good.

You need to do more testing/measuring of the Rectifier Unit voltages to determine whether or not one or more power supplies have failed.

Sorry Mike forgot again

It's a ts830s

I will print this out and get back to you

Congratulations!

I got the same euphoria over my first QSO with the Marshall Islands on my 35 year old TS-820 when she came out of the shop earlier this year. Purchased it in the Spring of '78 while stationed in Germany. It was such an improvement over the Tempo I I was using that I thought it would be my last rig! Well. Not quite, but the performance puts the 820 up there with the best, and she's still going strong today!

Barry,

Congratulations on working some DX. It's fun working DX.

Having said that. you did say what type of wire antenna you are using.
If it's a dipole, did you use the formula

468 / <freq in Mhz>

to achieve the overall "ball park" length of the antenna?

You also said the SWR was high. Did you trim/adjust the length of both
sides of the antenna equally for the lowest SWR to achieve maximum power
transfer to the antenna?

If you have not adjusted the length of both side for the lowest SWR then
I recommend doing that. Your antenna will work much more efficient by
doing that.

Don,

If the dial lamps, filaments, and fan are working/running, the Rectifier Unit is providing the correct voltages, but the digital display is dark, then I suspect the PLL Unit has changed states to "UNLOCK". This could be caused by a number of things such as bad/corroded connections in PC board plugs, bad/corroded grounds at the PC board mounting screws, bad connection in the remote VFO DIN socket switch on the rear panel (embedded remote VFO DIN socket switch controls the application of 9VDC to the internal VFO), or loss of required RF signals to the PLL Unit.

But first, as I said, you should check the Rectifier Unit for all the proper voltages before doing anything else.

Mike

I had my meter on dc and not ac so the 12vac is ok duh
Ac-800 i get 344 Ac-400--278 Ac 300-246 Ac-200-190 Ac-100-88
Ac-14-9,5 and HV- nil
The driver and the finals light up ok

Did not say the rec board was bad,just that there was a problem there
before and looks
likeR14 was replaced

Sounds like Barry has an EDZ made for 20M, or 2X5/8 wave elements centerfed.You need to feed it with a 3:1 balun if you have 50 ohm feedline but I don't think that is possible with a commercially available transformer.
I have a 90 ft dipole that has some gain on 30 and 20M but ZI use balanced line and a MFJ 974 balanced tuner and it works great..

Where did you get 492 ?????
A halfwave wire dipole is 468/F=feet.
This antenna is definately not a halfwave, more like 2X 5/8 waves on twenty meters !(EDZ ant)

You new guys really are something else, when you have your first contacts on the air with the South Seashell Islands or Lower Mongolia. :D
I remember my first REAL THRILL of DX was working from MI to just West of St Louis, MO with my one tube Home Brew transmitter running 6W (DC input) on 80Meters. WOW it was a big deal for a high school kid with no income or rich relatives then.
My next biggest Thrill was working all the way to the West Coast of Oregon with my next rig, a WW2 surplus 80 Meter ARC5 with a homebrew power supply and regulator made from scrap TV parts.
It was about 8 years later when I started working outside of N. America when I got on 10M.

Definitely experimenting - this is 50 feet of 14 gauge double speaker wire spliced into another 15 feet to go into the tuner, so I split the speaker wire so it is in a Y configuration. The upper part of the Y makes up 2 44' legs. One 44' leg goes to the front yard, and the other 44' of the leg goes to my backyard, and it is resting on my roof.

The Norcal dipole info I was going by had 44' legs, so I wrapped the remainder (6') of each of the 2 legs several times into PVC couplers (rather than cutting it off yet). Polyester rope goes into each PVC coupler and back to a tree to anchor it, about 7' off the ground.

The spliced in part of the double speaker wire, approximately 16' attached at the end of the Y legs, goes into the house into the MFJ 949E tuner, which allows for both wires to attach at the back.

It is probably at most 14' high since that's the peak of my roof. For now until I have my trees trimmed after a storm felled my highest one last week I have to wait to try to get it any higher.

I heard more on this setup and talked to more people DX than I ever have, but I've only had an 88' endfed antenna previously.

Don,

Don't measure the Rectifier Unit's high voltage output at the "HV" terminal. The "HV" terminal is for the "HV" metering circuit, the voltage is very low at that terminal. Measure the Rectifier Unit's actual DC high voltage at the Rectifier Unit's "800" terminal, that's where you will see approximately 920VDC (no load voltage/standby voltage).

If R14 on the Rectifier Unit is bad, for example it's burnt open, there will be loss of bias voltage in the 830. Problems in the bias supply not only affect the driver tube and the other circuits that use the -C supply, but also the final tubes. For example, loss of the bias supply (Rectifier Unit's -C supply) can result in both final tubes conducting to saturation levels, even in standby (transmitter is not keyed) which will turn the final tube plate RED, not to mention that D7 can also fail adding to the loss of bias voltage from the Rectifier Unit.

Also, ALL of the hybrid high voltage power supplies are "Voltage Doubling" supplies. Therefore, you will not see 800 volts on the transformer AC terminals as you might expect, the AC voltage will be much less. I recommend you study power supplies in the ARRL handbook so you understand how power supply in general and especially voltage doubling supplies, work. You should also study capacitors as well, especially connecting capacitors in series.

Capacitors connected in series do NOT calculate the same as resistors in series. For example, the 2 HV filter capacitors are connected in series which results in a total capacitance of "50ufd", not "200ufd" as you might think. The following formula will calculate the total capacitance of 2 capacitors connected in series:

C1 x C2 / C1 + C2 = Tc

In the case of the 2 HV capacitors in the Kenwood hybrids (2 x 100ufd at 500VDC each capacitor);

100 x 100 / 100 + 100 = 50ufd

The total safe working voltage of the 2 capacitors in series is 1000VDC

500 + 500 = 1000VDC

If 2 capacitors of different values, such as 30ufd (250VDC) and 50ufd (450VDC), are connected in series, the same formula and the same addition of the individual capacitor's working voltage is used resulting in:

30 x 50 / 30 + 50 = 18.75ufd

The safe maximum working voltage is:

250 + 450 = 700VDC

There is another formula to calculate the approximate voltage that is applied across each capacitor connected in series that's connected to a source voltage and that formula is:

Cv = TC / IC x Sv

Cv = Voltage across each capacitor
TC = Total Capacitance of the capacitors connected in series
IC = Individual Capacitance value
Sv = Source voltage

I mean no disrespect to anyone but the above formulas are all part of what I have been referring to many times on this group as learning "Basic Electronics" and every ham should have studied and thoroughly understood these topics, as well as many other topics, before taking the license exam.

The Norcal dipole is a shortened dipole and is using the speaker feed line a part of the radiator. All shortened diodes represent a compromise. I think you may be better off with a G5RV but go ahead and experiment with this antenna. You will not be trimming it to resonance as it is not a resonant dipole.

I assume your goal is a multband wire antenna. Ideally best one is 135 feet of wire in flat top fed with approx 45 feet of ladder line or open wire line to your T match tuner. This antenna will work very well on 80 thru 10 meters.

Most of the 88 foot designs I have seen are a compromise. I think Tom Rauch did some testing on them and posted results on his website.

If you do not have room for 135 feet in flat top or inverted vee config then just use as much wire as you can get in the flat top portion and whatever length of feedline you need to get to the shack. Some lengths of feeline will work better than others and you can read up on which lengths to avoid.

Some folks transition with a balun to coax at house entry point.

You dont care about SWR. SWR will be all over the place. Tuner is there to present match to your rig.

Ideally you should use ladder line or open wire feeders to the center insulator of the antenna, but I have used 300 ohm twin lead, zip cord, twisted pair etc. Ladder line is the easiest to run directly from center insulator directly to the tuner.

If you do transition to coax at house entry point make it as short a run as possible and use a good low loss coax and some folks parallel up two pieces as there will be very high SWR in this transition feedline.

Thanks Terry, That's why I asked here where I needed to cause I don't feel I'll be flamed. I understand what I was doing wrong. If it pegs the meter should I reduce carrier control a little? I have a power meter and some other test equipment, vom, vtvm, I want a signal generator but can't afford it. I wish you lived near me so you could teach me about the electronics in these rigs. I'm interested in these and older rigs and want to be able to repair them myself. Any idea why the send switch on the 530 works on all bands but 20 meters? I appreciate your knowledge. Thanks again and Peace be with you! 73 Richard KM5WX

Other things I am imagining that I could do with these modifications:

Play prerecorded cq calls or contest exchanges, or any audio out of the computer that I had a use for, such as replaying a recording of someones audio back to them, or a funny sound effect or two if chatting with a friend.

Record audio from the radio onto the computer.

Phone Patch, or "cross radio repeat" would be possible.

Endless options I guess, I am just excited thinking about the possibilities.

Thanks for any input,
Carl - N8FU

43576. TS-830s External PTT, and Line In Jack mod...

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-23 19:49:10 UTC
From: Carl Payne
Topic: 43575 Message: 43576

I have been brainstorming over ways to get my TS-830s as computer interfaced as possible, and here are a couple ideas I've had. I would greatly appreciate it if someone would let me know if I am over simplifying this, or missing something.

I would like to eventually have a foot-switch for PTT, for running a nice boom mounted microphone through a mixer, and potentially for computer keying of the ptt as well. I really don't like the idea of having a mess of things hooked up to the mic jack on the front. So my thought was to take some shielded cable, and solder it on somewhere on the back of the mic jack, to pick up the ptt and ground, then run it to one of the spare holes on the back panel. I was thinking a 1/8' mono jack would fit nicely in the spare hole. Is it really this simple?

The only other thing the rig is missing is an audio line in jack. So I figured the same thing should work for that, using the other empty hole in the back. Just pick up the mic input and ground off of the mic jack inside the rig, and run it to a 1/8' mono jack on the back.

I also have a TS-520S, and it seems like these two additions would make it just as capable as using the 520's phone patch connectors to run digi with VOX.

I'm new to hooking up external things like this to the radio, so I am sure I am missing something. But it seems to me that these are the only two things missing on the TS-830s and the usual way around this is to make an interface at the mic jack on front of the rig. I am thinking that these two jacks would give me everything I need to plug straight into the computers sound card and run digital modes. I'm thinking the PTT jack would be mostly for a foot switch when I get the microphone and mixer set up, but should be usable with a TNC interface as well. I figure it's just as easy to let the VOX do the work for digi modes, but maybe I could even add a splitter adapter to have both working simultaneously?

Other Thoughts:
Is there a way to create a line out that is separate from the radios volume control? So that I could do psk or whatever digi mode without having to hear it through my speakers?

Would the computers audio out match up well with a home-brew line in jack that I am thinking about?

Is it much better to use a TNC such as rig-blaster or signalink vs. just going straight to the sound-card?

I'm also interested in the idea of hooking up a small SDR receiver to the IF out jack that I have seen on some YouTube videos. Looks pretty cool.

And last but not least, is there a much better use for the extra empty holes on the back panel that I am not thinking of? And is this all just a pipe dream that is too good to be true?

I appreciate any advice I can get on these topics,
Carl - N8FU

Now my question is why are we mixing ivory tower theoretical formulas with formulas used in practical construction of real antennas ?? It tends to confuse the new guys who never had tried to fabricate a simple antenna.

Now my question is why are we mixing ivory tower theoretical formulas with formulas used in practical construction of real antennas ?? It tends to confuse the new guys who never had tried to fabricate a simple antenna.

Mike
Thanks for that info
There is 929 volts VDC on the units 800 terminal,so the problem lies in another area
R14 is good also
I did have a problem with loading and arching before the rig went silent

Don,

If you had arcing "with loading" I also suggest you check the variable caps on the load, plate, etc. to make sure none of the movable plates short to the stationary plates during any part of their rotation. You need rotate each cap through its entire range while checking the surfaces very carefully under a good light. You may find some "spot welds" on the plates. The pitting caused by the arcing will make a plate more susceptible to future arcing due to the sharp peaks at the edges of the "craters". It can be difficult to smooth them out but it can be done if you take your time.

Topic: 43550 Message: 43581

Yes if the meter pegs just reduce the Car Level control to get the meter pointer off the peg. Bring it down to 2/3 to 3/4 of full scale with the Car Level pot and then peak it with the Drive Control. That means turn the Drive control back and forth until you see the maximum meter deflection. If you are tuning up at 7.200 mhz into dummy load for example the meter should peak around 1200 on the Drive control if your Coil Pack alignment has been done properly.

I assume you mean you have no ALC indication in Tune mode on 20 meters. If so have you tried running the Car Level pot to full CW position? If not try that first. It could be as simple as a misaligned 20 meter Drive Coil or something potentially worse like a bad band switch contact. If bringing Car Level up to full CW position does not result in any level of ALC in Tune mode come back and ask again.

Do you have the owners instruction manual? If so you can read in the Maintenance section how to peak the 20 Meter Drive Coil.

You can also try cleaning the bandswitch contacts.

Terry K9TW

>
> Thanks Terry, That's why I asked here where I needed to cause I don't feel I'll be flamed. I understand what I was doing wrong. If it pegs the meter should I reduce carrier control a little? I have a power meter and some other test equipment, vom, vtvm, I want a signal generator but can't afford it. I wish you lived near me so you could teach me about the electronics in these rigs. I'm interested in these and older rigs and want to be able to repair them myself. Any idea why the send switch on the 530 works on all bands but 20 meters? I appreciate your knowledge. Thanks again and Peace be with you! 73 Richard KM5WX

Hi Ken

Thanks for your reply
I did bring it back from the dead with Terry's help,but i turned it on
the other day and all went silent[no readout,no sound]
I thought maybe the power supply had shorted out,but that is not the
case as per mike's help.
This rig has been not quite a nightmare,but a real learning
experience.Ebay special.
As i do have a few Hybrid rigs i can take my time with it.
I started the teck stuff very late in life as i was mostly a DX
chaser,but i now enjoy this part of the hobby more than operating.
I think the problem might lie in the final cage area,,but will take my
time for sure,as time i have

Topic: 43556 Message: 43583

Have you gone to audio board and measured the 12vdc, 9vdc and 3.6vdc RF-1 voltages yet. If not it is next logical step. OK to measure power supply voltages, but the radio likes to see these voltages where they are used at and not where they are produced at.

If all the low voltage supplies are good then I would focus on restoring the Receiver first and not the Transmitter. Arcing over the Plate load capacitor plates will not cause no RX mode. No reason to open PA cage at this juncture.

When you say no Receive that means a lot of different things to different people. No audio?, no off air signals?, no marker signal?. Pretty easy to check the major receiver blocks after you confirm low voltage regulators are working.

You can start at front end or at audio output. Usually easiest to see if audio stage is working. If you do not have an audio generator or signal tracer you can use just about any audio source you have (MP-3 player, lap top etc to inject audio signal at the AF Gain pot to test the Audio stage.

As a rule I always get receiver going and then move on to the transmitter. Just my approach.

It was very common back in the day for antenna primers to explain that 492 was used to determine the electrical length and that you needed a constant to take into account the length to diameter ratio and practical height that hams use when erecting a dipole. K was typically considered to be 0.95. So using 468 or 467 is used to determine the actual physical length of a half wave dipole. Add 5 or 6 inches to each end to allow pruning and that is all a new person needs to know.

This isnt "Engineer Training" this is fundamental Novice class license training. Nothing wrong with a brief explanation of where 468 comes from. This use to be a technical hobby.

The real problem is you all rushed off to tell this fellow how to tune his dipole to resonance to address his 5:1 swr. The minute you saw 88 feet you should have realized he was most likely trying to build a Cebik multiband doublet. Has been many articles in the literature on this antenna as well as the 44 foot version.

Yes it does function as an extended double zepp on 20 meters and does have some gain on that band.

He did pretty good for his first antenna and very modest investment. I would never have thought to build one. In my day a half wave dipole on 40 meters was first antenna we all built and used it as 3/2 on 15 meters. Of course then we were crystal bound and first rig wasnt a Kenwood hybrid. A multiband doublet wasnt thought of until much later.

As I said he can probably improve on its performance if he replaces the speaker wire feedline and goes with 450 ohm ladder line with a 4:1 current balun at the house and a short run of RG-213 to his T-match. Just some enhancements that may not realize much performance improvement based on how well it has worked for him. I also agree with the other fellow who suggested some additional height. YES I know propagation is a major player here.

He is having fun and I hope learning in the process.

Don:

Just close the loop for all of us and I am not saying you dont need to check for Plate Load cap for arcing at some point if you did hear arcing and frying sound. Just would not be high on my list now unless you know you had a coax or connector or antenna feed point problem that resulted in a very high impedance being presented to your SO-239.

Loading rig into 50ohms should see approx 71rms volt or approx 200 P-P volts across your Plate load cap. The plate spacing is designed for this voltage level. If you introduce a high impedance due to a bad connection say 5000 ohms the voltage will be 10x that or approx 707rms volts or approx 2000 P-P volts. Plate load cap wont like that.

Height is really the prime determining factor on how well you are going to "reach out" with almost any kind of antenna. I dare say that a dipole at 100 feet would probably equal almost anything that could be put up at lower heights. But of course, not that many can afford a 100 foot tower, and anyone who can is probably going to put at least a three element yagi on the top of it, just to get that extra boost in ERP .

Thanks, Terry, for backing me up on the thought of feeding a "newbie" with a little more information. It may be more than he asked for now, but the knowledge should be helpful to him in the future.

Terry
I should mention that i have no IP reading and no HV reading at all
It's just like a fuse has blown.
The fuse is fine as we would not have fan,and panel lamps on ,but i am
sure you will straighten me out on this

Jim:

There will always be different opinions about this subject. Of course there are things that for now they need to take on faith. Even today lite bulbs finally come on for me after all these years.

I could never be happy being an appliance operator. Part of why I run Kenwood hybrids. The newer rigs are starting to approach black box with "no user serviceable parts inside" label which would sure be no fun for me.

New folks cant help being born at time they are and how entry into the hobby has changed. I would not have missed the late 50s and early 60s dragging TV chassis home to strip and build power supplies, converting military surplus rigs, or building kits and the fun Novice days. Can you imagine having a Kenwood Hybrid as your Novice rig. I couldnt afford one until I raised my family!

Not possible to give these fellas the experiences I had early on that gave me a good fundamental foundation. However, I will continue to try to give it to them a spoon at a time. Hopefully some will like the taste and hit the books.

I think it is a dis-service to them to assume they are not interested or have no aptitude and not make it available to them. I am in the camp of making it available to them and letting them decide.

Terry K9TW

Do you mean you have no HV reading on your panel meter?

Are you comfortable measuring HV at top of the plate choke L2 in the PA cage?

With rig off and unplugged and HV caps discharged you can do a quick visual in the PA cage. Look at the Plate choke to see if any signs of discoloration. Look at base of choke and see if the rf bypass capacitor seems to be dark and/or split open. Look at the small VHF choke at right angle at base of big choke to see if it appears discolored or blown in half.

If all look good then energize rig and measure voltage at top of main choke L2. You can connect your meter leads (make sure good positive connections with probe alligator clips so they dont jump off) while rig is unplugged and then power it on and not have to touch the meter to take the reading. Down power and discharge HV caps before removing meter test leads.

If you have good voltage at anodes of the 6146 tubes you most likely have lost your HV voltage divider resistor string R5 thru R8 on the Rect board. If so replace all. Can buy precision resistors from Mouser.

If you have good HV at top of L2 and no Ip likely have lost your four 20 ohm cathode meter shunt resistors on the Final board due to 6146 arc over.

43591. Re: [TS-520_820_530_830] Re: Power Supply

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-24 02:35:46 UTC
From: Don
Topic: 43556 Message: 43591

Yes that's right
Will look at tomorrow

Thanks
Don/Ve2ud

"Most of the 88 foot designs I have seen are a compromise."

Actually, an 88 foot antenna, center-fed with balanced line, tuned with a simple tuner and a balun is an EXCELLENT all-band antenna...

Don't know why Barry settled on an 88' length, possibly because that is where his "sky hooks" are... But in any case, he (as someone else noted) has come up with a 20-meter Extended-Double-Zepp, which is one of the best all-band antennas known to man...

Although I have room for the 135' version, I use an 86' flat-top, center-fed with 300 ohm TV lead-in... It is 45' high, using trees for sky-hooks...

It works very well on ALL bands from 160 thru 30 meters, and on 20, 18, 15, 12 and 10 meters, it is one HELLUVA GOOD antenna... My little ol' TS-830S, with about 100 watts output, usually gets the rare DX on first attempt...

Do yourselves a favor... download the "Demo" version of EZnec... Model a 20 meter EDZ, and take a look at the resulting patterns on all bands...

Notice the spherical radiation pattern on 160, 80/75... Most of your radiation goes straight up where it will reflect from the iononsphere and give you excellent local communication... (local being 200-300 miles on 160, and 200-500 miles on 80/75)... 40 and 30 meters are even better, but the EDZ really starts to shine at 20 meters with it's low angle of radation and almost 3 db gain over a dipole... On 18 meters, the pattern is 4-leaf clover with maximum radiation at about 20 degrees... On 15 meters, still the 4-leaf clover, but max radiation is now at 15 degrees... 12 meter pattern is multi-lobed with maximum radiation at 10 degrees... 10 meters, a multi-lobe pattern (10 lobes, looks like a big spider) with max radiation at 10 degrees...

On 20, 18, 15, 12, and 10 meters, you can "pick off" the DX before the "big-boys" can bring their beams around...

Nice going Barry... Glad there is still someone out there that has "figgered out" that antennas are not nearly as complicated as some would have you believe...

buck K7WN

Glad it is working for you and fun to break the pile ups.

Curious how you load into it and adjust tuner and the 830 Pi-network as you move around the band looking for the pile ups to pick off.

Do you tune slightly off the pile up and key rig and make your on air adjustments?

Wonder how it compares to three element tri-band yagi on receive?

No need to download EZnec
http://www.tomochka.com/na7u/doublet/w4rnlbackup.html

I forgot to add this which discusses the 88 foot antenna as a "system" and not just the flat top. Have to be able to get the power to the efficient radiator.

I have no personal experience using a 88 ft multiband antenna. Pretty sure I said much of the literature puts it in class of all shortened antennas as being a compromise antennas.

I do have enough experience with AB testing on the receive side of dipoles/doublets versus directive antennas and hard to beat beams of any kind wire or otherwise.

However I am a big fan of experimenting with all kinds of wire antenna configurations and I think I said that and offered suggestions on how he could enhance his existing Cebik doublet.

Hopefully he wont experience any arc over in his MFJ tuner.

For those who don't have access to an antenna handbook that covers this (and other) wire dipole antennas, here is a link to the Cebik article on the web as a PDF file. You can download it and have a copy handy at home, or print it, or just read it on the web from here. I keep a copy archived locally, though, because it is such a good reference for these sorts of antennae.

http://www.users.on.net/~bcr/files/backyard%20wire%20antennaes.pdf

This is just to save folks some digging around. It's not the only article by any means, nor possibly not even the best one. It's just one of them, and I find it to be very good for the basic purposes of building one. The drawings are very clear, in particular.

(If I could cabbage on to a three-position antenna switch, I would consider a triple EDZ triangular array, like the one which is shown in this PDF file article, in my back yard. I've got three trees that would probably work for supports. Almost as good as a big beam, without the wind load, which is a SERIOUS thing around my neck of the woods. Last night we were treated to another dose of high winds- 60 mph / 100 kph, and not just gusts. Those were sustained wind speeds, for many minutes at a go. Putting up a big beam antenna around here is just asking for a pile of recyclable aluminum scraps.)

We should really let this go. I just wanted to help him optimize the Norcal design and get it up in the air more if he can.

This started when someone objected to me saying that a shortened multi-band antenna represents a "compromise". Compromise isnt a dirty word and I stand by my statement.

All multi-band antennas (that includes loops)and shortened versions of them whether they use traps or loading coils or other mechanisms represent a "compromise" over a full size single band antenna. Compromise can be in gain, directivity, bandwidth, ease of feeding, convenience of getting the feedline into the shack etc. Read this a couple of times if you still dont get it.

When you can come up with a coax fed multi-band antenna for 160 thru 10 meters that matches performance with full size single band antennas you will be a rich man. We have all been searching for that antenna.

I do not dispute that the 88' multi-band antenna if trimmed appropriately can approximate a EDZ on 20 meters and exhibit some gain. Most multi-band antennas if erected high enough do exhibit gain on the higher bands. The lower bands is where the challenges start to manifest themselves more.

As to the owner performance reports for these antennas most if not all are subjective and often fail to give any credit for propagation. If you dont believe that then how do you explain being able to copy 10 meter 100mw beacon carriers on just about any antenna? Ok maybe not on a coat hanger.

I stand by my comment that a shortened multi-band antennas represents a "compromise" antenna. You put up what you can based on the limits of your lot size and your budget. About the only area where hams can still experiment with a modest budget and have some fun.

This never was about a 20 meter EDZ. Not sure how it got to this point. I think because someone thought that is what he was trying to build and he was not.

I am going back to trying to help Kenwood hybrid owners with Kenwood problems.

Terry
All voltages checked out ok.on the power supply and the final section
The arching might have been caused by a bad solder joint at the top of
the choke,,PS-2
Now i just have to find our why the relay is not kicking in to turn the
rig on

I agree with Mike, but I would like to thank Terry for the link to the Cebik article which I found very useful. Back to my hybrids.

73s, Scott, N6CIC

I too want to thank Terry for his link to the antenna information.

And in the same spirit I would like to provide the Group with a link to a very impressive free collection of data, specifically focused on vaccum tubes and older electronics but also of general use:

http://www.tubebooks.org/technical_books_online.htm

Terry
I downloaded that color schematic and it's a lot better on my eye's to follow.
I measured all the boards for the dc voltages and there is none.That would explain why the rig will not fire up.
I know all the rectifier didoes are good as i tested them to make sure.
Is the 12 volts produce from the rec board?.I see a spot on the rec board marked 12,but i get no reading from it.

Dont need any relays to change state for Receive. Rx works on the NC contacts of the relays.

I thought you said you had no HV indication on your panel meter???

Sounds like you are talking about choke L1 and junction of PD-2 which is 6146 screen grid voltage.

This is first I have heard about a relay problem. What relay are you talking about? The Aux relay on the AF board or the TR relay under PA cage or both? They should both key when you flip to Send. If they do not then you may have a bad Q17 relay switching transistor on Audio board. Never seen a bad relay operating coil.

Before assuming bad Q17 check Molex connectors 4 and 5 on the Audio board. Carefully pull,clean, and re-seat.

You can test Q17 by grounding Pin 5 of Conn 5. If no action try Pin 1 of Conn 4.

If grounding SS line at the Audio board does not result in keying the relays still could be a bad solder connection at the molex connector pins. Measure dc voltages at TP-3 on audio board as you flip to Send and/or apply ground on the SS line. Correct voltages are on the schematic (approx 11.9vdc in Rx and approx 10.5vdc in Tx). If you have correct voltages at TP-3 and still no relay action then measure voltage at Collector of Q17 which is Conn 5 Pin 6 RL. Should be 0 in Rx and 12vdc in Tx. If Q17 is bad need to replace it and the flywheel diode at same time.

Bad relay switching transistor does not explain no Rx???

Robert:

You are correct a great site. Just some really big downloads, but some real treasures. J. F. Riders VTVM primer is great for understanding why VTVM was invented and how to use it to troubleshoot tube radios. I think I learned how to check for leaky interstage coupling caps from this book many years ago.

Thanks

Re the 80-125 ft flat top centerfed antennas;
The only compromise for an "allband" 88-125 ft Centerfed wire is using balanced feedline where you will need a balanced input tuner in the shack to have the best efficiency. No way is it a Shortened antenna if you use it on the bands where it is at least half wavelength. My 90 ft dipole works the bands from 60M up to at least 17Meters. Since it is less than a halfwave on 160 and 80 it fails badly there.

Subject: [TS-520_820_530_830] Re: Worked Czech Republic, France and Poland with the 820 on $12 of wire

I forgot to add this which discusses the 88 foot antenna as a "system" and not just the flat top. Have to be able to get the power to the efficient radiator.

I have no personal experience using a 88 ft multiband antenna. Pretty sure I said much of the literature puts it in class of all shortened antennas as being a compromise antennas.

However I am a big fan of experimenting with all kinds of wire antenna configurations and I think I said that and offered suggestions on how he could enhance his existing Cebik doublet.

Hopefully he wont experience any arc over in his MFJ tuner.

That 12vdc point is the input for the SG relay. If you have no regulated 12vdc from the Audio board will have no 12vdc here.

You need 14A voltage from the rectifier board to the Audio Board. Measure at the 14A terminal. If good there then measure at the Audio Board at the 14A terminal. If bad there then check the AC input voltage across AC 14 terminals to see of transformer secondary winding is good. If have ac then check the bridge rectifier diodes.

Voltage at 14A is 120 hz AC from the bridge rectifier on the HV Rec board. It has not been filtered yet by the C-R-C filter on the Audio Board.

If you have approx 17.9vdc at the 14A terminal on the Audio Board and no 12vdc at the 12vdc terminal post on Audio board you have a problem with the series pass regulator circuit. Could be bad series pass transistor Q34, but need to troubleshoot to determine that.

Here are some approx voltages:

1. Across AC14 = 15.4vac
2. 14A to chassis ground = 17.9vdc
3. 12 dc output post on AF board = 11.9vdc

Note: You may want to consider cutting a piece of cardboard (off back of yellow 8.5 x 11 writing pad for example) and lay it over the HV filter cap area while taking these voltages so you do not inadvertanty touch or drop something in that area. I have a piece of lexan that I use from time to time to cover this area and the HV rect board.

Good evening all,

Thought I would give closure to this post. I have completed all checks on this rig and the only thing out of spec was the IF. After making those adjustments it is up and running FB. Receive sounds terrific. I did get a little bit more from alignment but not a whole S unit on any band. Everything but the PLL and Counter boards look factory installed and the final tank is spotless. No new parts anywhere that I can see. I am of the opinion that the 2 boards were cannibalized for another rig and the old boards placed back in. I did find half of the screws missing when I removed the PLL board. So, all in all I have had a good week working on this Hybrid and finally got to understand the PLL circuit. This was the only board I had no experience on. Thanks to all who offered their opinions and thanks to Terry for following me thru this. Great experience and another old girl is back on her feet. I put a fresh painted cabinet on her and she shines like new. Just one scuff mark on the upper right corner of the bezel. I may do a little touch up there to make it perfect. Forgot to mention, the narrow SSB filter works fine but I can't stand to listen to it. Can not imagine anyone using it but that is just my ear's opinion.

Take all kinds of folks in this world. A note or tag on the boards would have helped. I generally dont store my parts harvesting boards in a rig. That would present a challenge to any future owner.

Nice work Don. Enjoy. Terry K9TW

Terry
First i must say excellent instructions.
I had to think about the measurement across AC14,but the brain kicked in
and said both leeds across it.
So the results are
Across AC14=15.5
14A=19.5
12dc output post on AF board= NIL
Next step
73

Don/Ve2ud

Terry... I didn't intend to "step on anyone's toes"...

Just thought that a more complete description of the EDZ would possibly encourage some of these guys to build a simple, yet very good, antenna...

Truth of the matter is that I enjoy this forum, and when my old TS-830S is in need of repair or maintenance, this is the first place I come looking for pertinent information...

==========
Now, a few comments on your and others comments
==========
Re: Jim S comment: "Height is really the prime determining factor on how well you are going to "reach out" with almost any kind of antenna."

A true statement Jim... Height is the "name of the game" when it comes to antennas...
==========
With Jim's comment in mind, I will comment on the following statement:

Re: Terry's comment: "No need to download EZnec
http://www.tomochka.com/na7u/doublet/w4rnlbackup.html "

Yep... the woods is full of published antenna patterns... but NONE of them will match your particular set of antenna erecting problems... Keep in mind Jim's statement about height... You will not get those published antenna patterns unless your antenna is at least a half-wavelength above grade...

And that is where EZNEC "shines"... You can enter YOUR particular parameters into EZNEC and see how the antenna will radiate when cut to fit your lot, and stretched between your sky-hooks...
==========
Re: Terry's comment: Glad it is working for you and fun to break the pile ups.

Terry... I have been licensed for about 60 years... I have used almost any kind of antenna you can imagine... For many years I used a 1/4 wave inverted L on 160 and a full sized 1/2 wave dipole on 80/75... But, I was primarily a "beam and tower" guy, with stacked mono-band yagis atop a 70' tower. (3 elements on 20, 3 elements on 15 and 4 elements on 10 meters... In the early 90's one of those Florida hurricanes turned the yagis into junk and I erected a two element tri-band quad in their place...

But, Alas, I got too old to climb towers... and I put up a 20 meter EDZ...

That is when the real fun started... I found that the EDZ worked so good on 160, 80 and 75 that I took down the inverted L and the 80/75 meter dipole... The EDZ also worked very well on 40 and 30 meters, and extremely well on 20 meters and higher bands...
==========
Re: Terry's comment" I forgot to add this which discusses the 88 foot antenna as a "system"

and not just the flat top. Have to be able to get the power to the efficient radiator.

Yep... and the "system" includes the antenna itself, transmission lines, tuners, baluns, etc..

My particular system is an 86' flat-top of #12 stranded wire, 45' high, center-fed with 57' of 300 ohm TV twin-lead connected to a Walt Maxwell bead-balun which is mounted on the exterior wall of my house and connected to my home-brew pi-net tuner using a 6 foot length of RG-303...
==========
Re: Terry's comments: "Do you tune slightly off the pile up and key rig and make your on air adjustments?"
"Curious how you load into it and adjust tuner and the 830 Pi-network as you move around the band looking for the pile ups to pick off."

I seldom tune-up "on the air"... Other than when adjusting your tuner for a brand new antenna setup, tuning up "on the air" is just not necessary...

1.) When I use an antenna for the first time, with the "Bird" in the line, and with the 830 powered down to QRP and tuned to the 50 ohm dummy load, I switch from the dummy load to the antenna and adjust the tuner for lowest swr at the point in the band where I usually operate... I then record the settings of the rotary inductor, the input capacitor and the output capacitor for each band that I intend to operate... (Note: These settings are just for initial adjustment, and will change when the 830 is powered up to 100 watts output)

2.) Next, I tune the 830 to 100 watts output into the 50 ohm home-brew dummy load... (The tuner controls are set to the points determined in step 1.) When switching from the dummy-load to the antenna system, I DO NOT RETUNE the 830 as it is tuned for a perfect 50 ohm match... If any "touch-up" is needed, I do it with the tuner controls, which is, in effect, adjusting the tuner to the 50 ohms that the 830 likes to "see"... I then record the "touched-up" tuner settings for each band...

For example: If I am going to operate on 20 meters, I set the tuner controls to the "touched-up" settings for the 20 meter band (in my case, 14050kc)... I then put the TS-830 VFO on 14050kc and tune it for 100 watts output into my dummy load... (about 225 mils of "dipped" plate current)... I then switch the output of the TS830 from the dummy load to the antenna system... No further adjustment is neccessary... No "on the air" tune-up is necessary... I can QSY from 14001 to 14100 without re-tuning the TS-830, or the tuner... The SWR stays below 1.2:1
==========
Re: Terry's comment: "Wonder how it compares to three element tri-band yagi on receive?"

Actually, it compares fairly well... Of course the EDZ doesn't have the ability to rotate and doesn't have the FB or FS ratio of the yagi, but it "hears" very well, and doesn't have the expense or maintenance problems associated with rotating a large antenna on a 70 foot tower... Also, the yagi is virtually useless until the antenna "bears" on the DX station QTH... I have many times experienced the frustration of listening to some guy with a "pea-shooter" pick off the DX stations while I was waiting for my antenna to come around to bearing...
==========

Yes... I am "long-winded" but just trying to respond to Terry's queries...

And I realize that someone has already complained about having to read about "antennas" on the forum...

But, all things considered, it is good to have a report like Barry's... And, it just might encourage some of these other guys to know that it is still possible to build antennas and equipment that will "work the world"...

Don,

Terry answered that one in the message you attached. He said check around the series pass transistor (Q34) to see where the voltage disappears.

He said

If you have approx 17.9vdc at the 14A terminal on the Audio Board and no
12vdc at the 12vdc terminal post on Audio board you have a problem with
the series pass regulator circuit. Could be bad series pass transistor
Q34, but need to troubleshoot to determine that.
So will wait to see what he has to say.

Actually I didn't state that well in my last reply. What I read Terry to say was that the series pass transistor, Q34, might be bad, but you'd have to troubleshoot to see, I just think that he meant that the transistor MIGHT be bad, but could be something else in that area. I just took that to mean to check around the pass transistor circuitry. Maybe not though, just my impression.

Well the problem is that it is not easy to take voltage readings from the component side of the board to determine what has failed. Here are some possibilities that come to mind:
1. Open L5 choke- never seen one. If you are very careful you can get on the Emitter lead of Q34 and see if you have approx 18.0 vdc. If you do then choke is not open. If C83 was shorted and pulling down voltage it should hurt 14A rectifier diodes on HV Rect board. To take component side EBC or DSG readings I use a corsage pin that has a white pearl ball on the top and is about 3 inches long. I heat shrink them and leave room at top to clip on a mini-grabber test lead and leave just the sharp tipped point exposed on other end. Can do this with any small diameter sharp pin.
2. Next still being careful not to short transistor leads or short to aluminum heat sink measure the Base of Q34. It should be approx 17.25vdc
3. I have seen failed D26 reference diodes. Output voltage will usually drop to below 1 volt if this occurs.
4. Never seen any of the feedback transistors or error amp transistor bad.
5. With rig off measure resistance from 12vdc output terminal post to chassis ground. Should see approx 40 ohms.

Really after this would need to fold the board back and remove Q34 to test it. Would also want to check D26.

43617. TS-520s VOX flipping on and off in CW recieve

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-25 04:59:55 UTC
From: JDPuffer
Topic: 43617 Message: 43617

I recently hooked up my 520s after realizing that it had the 500Hz CW filter installed. I am having issued with the vox rapidly switching on and off while in receive mode in CW. It does not do this when switched to the dummy load, or when the volume is very quiet, or when in side band. I don't have a microphone plugged in, and it does it whether the CW key is plugged in or not. I've fiddled with the VOX adjustment knobs and nothing seems to affect it at all.

Any advice???

Hi Don
No problem,it's just i don't want to get ahead of the instructor.
First i will remove the board and do a inspection on it first,as in
solder joints,broken wire,ect
and then go with Terry's recommendations.

Buck:

Mike (moderator) has asked us to stop this thread so very quickly:

1. Glad to see you are using a look up table to facilitate ability to change bands and QSY without making full power on air matching unit adjustments. Good practice and I hope everyone new and old alike follows your lead.

2. My comment about shortened multi-band antennas in general representing a compromise relative to single band full size dipoles stands. I am not talking about a stand alone 20 meter EZD antenna.

3. I did not say that 88' or 44' multi-band antennas do not result in EDZ length on either side of the center insulator which results in a good bi-directional antenna on the highest band (20 and 10 meters).

4. It appeared to me that the builder was trying to model a variation of the NorCal QRP club multi-band antenna that uses speaker wire and had not set out to build a 20 meter EDZ. I was trying to help him improve his design. Glad to see he was trying this antenna and home building and not buying a ready built dipole.

5. Here is what Cebik himself said about the low band compromise:

"The 88' doublet offers flexibility and reliability if we are willing to dust off that old link-coupled tuner and invest in some high quality parallel transmission line.....
However, do not develop high expectations from 80 and 75 from the short wire element and possible line losses. However, as a back-up antenna or array, the 88' length may prove serviceable as a single compromise length with determinate pattern directions."

Updated 04-14-2000, 11-01-2004, 09-08-2005. ï¿½ L. B. Cebik, W4RNL. This item first appeared in volume 2 of the Top Band Anthology, pp. 19-33.

6. I did not find in any of Cebiks writings that he discussed the 80/75 NVIS characteristics.

I will be happy to have further discussion between interested parties off list as we all have email. Although discussing antennas and VSWR with hams is tantamount to venturing into politics and religion.

Sorry Mike no more from me.

Carl,

Have you tried turning the CW sidetone volume down, VR2 on the AF Unit, to see if that helps the problem? Try cleaning VR2 then adjust it for a normal sidetone in the speaker while keying the 520 in CW mode.

I forgot to mention that VOX DELAY is enabled in CW mode but VOX GAIN
and ANTI VOX are disable in CW mode. That is why the symptoms don't
change by adjusting ANTI VOX and VOX GAIN while in CW mode.

If your visual inspection does not reveal any open traces etc then maybe it would be best if you just replace Q34 and D26 while board is folded over. If you find D26 has shorted check R132 to make sure it hasnt shorted. More likely to find it drifted high.

I dont normally recommend changing parts that have not been proven to be bad but may be easier than powering the board while folded over and taking voltage readings? You can run board like this just keep AF gain down and dont run too long as you will have lost some heat sinking. Dont want to damage Q4 AF output chip.

Also, might want to consider replacing C84, C83, and C81 while you are there.

Terry
As those zener's can act like a fuse,i took D26 out and tested it.It tested fine,so i reinstalled it
and tested for 12 volts again,and checked the base of Q34 and both were fine.
I did not realize because i had the rig upside down that the rig had came back on,because i had no audio i could not hear it.
Maybe just resoldering the D-26 woke it up,but all the bottom of the board looked pretty good.

I have rechecked the connectors but still no audio yet.

So you are telling me you now have regulated 12vdc, regulated 9vdc and 3.6vdc RF-1 available on the Audio Board and no output from the Speaker?

This really sounds like a loose molex connection, dirty molex connection, bad solder joint at molex connector pins, cracked foil at molex connector causing an intermittent condition.

Do you have CW side tone in speaker if not what about headphones?

With just a few points of audio injection can find where losing it. Can start at Speaker and work backwards toward Produce Detector input or work from Product Detector input toward Speaker.

Terry
I still have to check the rest of the voltages,as it's such a nice day,i
need to do a bit of yard work
Yes i did test with the headphones and for cw side tone and nothing heard.

OK there can be a difference between no Audio and no Receive signal. Or can be one and the same.

I assume you mean no off air S-meter indications as you tune across the band and no Marker signal S-meter indication at the 25khz positions of the VFO range?

OK I do not know what you mean by check the rest of the voltages?

Now that you have 12vdc restored do the relays key?

Side tone in the headphones is a quick test absent any AF signal injection capability. Did you have normal sidetone before this latest failure?

Use of Moni assuming you have a TIF signal is also a quick test for the AF output amp and headphones jack.

However neither signal source tests the Q3 audio pre-amp path.

Sometimes having no RIF signal can fool you into thinking you have no audio, but in that case you should still have side tone.

If you have no Side tone and no Marker signal need to think what is common to this or is it multiple problems. First thought is low voltage power supply missing. Need 12vdc, 9vdc, and RF-1. Then need proper bias switching.

Anytime a radio is capable of being powered up and not blow the fuse the proper way to troubleshoot is with signal injection and signal tracing. Have to understand the required goes ins and goes outs and validate they are there. Once you find where signal is missing then you reach for the voltmeter.

Audio stage is typically the easiest to test. In old days a finger or jumper lead applied to wiper of AF gain pot is all you needed. Once you eliminate that stage you can move on to IF and RF.

If you are going to trouble shoot hybrids you really need to get an RF generator with internal AF modulation that comes out to external jack. You can inject RF and AF with this test set.

Other option is building a Signal injection/Signal tracer like the Hendricks QRP test unit or buy a Heathkit Signal Tracer like the It-12. The IT-12 cannot inject audio or RF so I would go for the Hendricks or get a RF sig gen. Even a Heath IG-102 or Eico-324 or similar LC type for starters is fine.

Terry
I just did all the connector voltage checks and all are ok,except were
you say 3.6 volts i get minus 6 volts.
The bands are the worse i heard them in a long time,so to say receiver
is not working might not be correct,so please disregard that.
The marker signal is there,i just can't hear it.I did plug a speaker
into the rear speaker out and a faith hum is there.
Maybe i pinched a wire somewhere?

Hope you take Paypal lol

Don:

I am totally at your mercy as to what you are seeing and reporting. I have to ask are you 100% certain that you have 12vdc at the 12vdc post on the audio board? Do the relays now key when you flip to send?

The Audio amp requires 12vdc and the RF amp and RIF Mixer requires 12vdc. Very odd that you had no 12vdc, removed and re-installed reference zener and report now having restored 12vdc.

If you go to RF board do you have 12vdc at Conn 6 Pin 2?

Are you saying at Audio Board Conn 9 Pin 5 you are reading -6vdc to ground?

If so the S-meter should be pegged full scale. Have you tried turning the AGC off and leave it off for several seconds and see if rx comes alive?

If this is the case go to IF board Conn 15 Pin 3 back by the 300 and 200 filter caps on the IF board and measure the AGC bus voltage. Make sure you are on Pin 3 and not Pin 1 as it has 300vdc on it.

If you have -6vdc on the AGC bus there is one common way this can occur. That is for AGC Amp Q10 to be saturated. This happens when you have lost Product Detector carrier null. Can be bad or dirty trim pot or shorted ring diodes. The BFO (LO) leaks back thru L12 and swamps the AGC detector diodes and drives Q10 into saturation. Q10 has -6vdc on its emitter. When turned on to saturation the -6vdc is applied to the AGC bus. The -6vdc is required to back bias the AGC detector diodes and set the AGC threshold level.

Should never have -6vdc on AGC bus. RF amp and IF amps will be turned off with that level of dc control voltage applied to Gate 2 of the devices. Should be +3.6vdc with RF gain pot full CW. You wont be able to read that level with a 11meg VTVM or 10 Meg DMM. Probably around 2.8vdc or so as meter Z will pull it down.

Terry
Yes odd in deed.Maybe it was the first one off the line hi hi
All the solder joints look dull,but it probably because it's old like me.
Just removing and reinstalling that diode made no sense to me as why we
got voltage's back
yes the relays engage now
I put the headphones on and keyed it[relay click's] and all i get is a
hum in the headphones
The 60ma ip is there,but i can't load the radio,no drive,no rf output now
Yes the 12vdc is ok at conn6 pin2
This is starting to drive me a bit batty and i sure it's getting to be a
bit much for you too.
We had it nicely going and puff away it went
Maybe when my brain and eye's have had a rest, i will recheck it all
I need a good boat anchor for my boat.

Don/Ve2ud

No it's conn7 pin 7 minus 6 volts

I should have not involved conn 7 pin,,i should have only followed the
red line [dc line] and that
being the case all connectors have the right voltages on them.
Nap time
Don

Don:

When you finished the PLL board repairs are you certain you plugged Conn 7 in? It is your Carrier Osc signal to the IF board.

Do you have a means to measure the Carrier Oscillator signal at Conn 13 on the IF board? If no Carrier signal there then go back to Conn 7 on PLL board and confirm it is there. If no Carrier there then re-seat Conn 8.

You need Carrier Osc signal to produce TIF signal. No TIF signal from the IF board and you will have no RF drive to your finals.

You also need Carrier Osc signal to recover audio at the Product Detector which is then sent to AF board to be amplified.

Does not account for why you have no sidetone, but could account for no RX and no TX.

I forgot to mention that you can check for Carrier Osc at TP-3 which is right next to Conn 13 on the IF board. Some schematics do not show TP-3. Level should be approx 300mv rms volts.

Terry

Sure i did,but later tonight i am going to start all over again from
board to board
and will report back with the measurements.
I have to reread some of the material you sent me.so i know i am on the
same page as you,as i don't want to give you false information to waste
your time.
Even tho it's much more complicated than my QRP gear,i have to use the
same overall approach.
When i get overtired or frustrated,i usually stop for a day to clear my
mind.
I really appreciate your patience.

Because my eye's are not what they use to be[plus a few other things]
i have to blow up the pdf file to about 400% to read it.
I am going to try to get my daughter to blow up a nice copy for me from
her work place so i can lay on top of my chest freezer and follow it
along as i did with my Heathkit HW9 as they made a nice one.
The freezer broke so instead of paying someone to take it out, i decide
to use the top as a repair work bench hi hi..

43639. Audio out of the rear socket Question

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-26 07:38:50 UTC
From: Kevin, Natalia, Stacey and Rochelle
Topic: 43639 Message: 43639

Hi Guys,

I am doing some audio management for my radios.

On the TS830 rear socket I see an audio out pin.

My question is, is this pin out suitable to plug into a mixer? I am guessing here that it would be a fixed level output (but I could be wrong).

Any ideas or input would be helpful

Regards

Kevin. ZL1KFM.

I will also be feeding the TX audio in from another mixer port. I have already made up a resister pad to bring the levels down to prevent overdriving the audio input stage. Pity there isn't a better audio input that would be better, suggestion, maybe look at tapping into the board and fit a socket into the back of the radio for mixer audio in?

Hi Kevin,

If you are referring to pin 1 on the REMOTE DIN socket, labeled "SP" on the schematic, then no that is not a fixed output. Pin 1 on the REMOTE DIN socket connects to the AF Unit plug 3 pin 1 which is the output of the audio amplifier. Audio that appears on Pin 1 of the REMOTE DIN socket varies with the front panel volume control. Do you have the 830's high resolution color schematic? If you do not have it then I can send it to you.

The sidetone is pretty quiet. If anything i would like to turn that up. What I don't understand is what signal is even activating the vox in the first place. The microphone is unplugged and sitting in a drawer. It does it with everything except the antenna unhooked. Seems to me that there isn't anything that should even know that the volume is there.

Hi guys (and girls).... Just a quick question..... I just purchased a 830s and LOVE that radio . Wow.... Quite a step up from the 520s that I have been using. I never want to go SS. I'll stick with the hybrids....
Easy question I hope.......
When I first turn the radio on, the S meter pegs to the right... I must have some control set too far one way or tother... Scars the dickens out of me. Don't want to look for a new meter. The meter functions just fine after that initial turn on.....Radio functions just great and glad I made the purchase....
Another observation.... I seem to be able to "drive" this rig a lot hotter than the 520s..... I am getting 140 watts out and could never get that with the 520s even after "recapping" the rig. Is this typical of 830s..... To get ahead of your next response, NO I do not keep it there. I settle on at 120watt or less. I remain impressed by this radio. Whew!.....Like it, like it ,like it.....
Thanks for any help you can offer......

Kevin,

Look at page 15 of the TS-830 user manual, section 15 "REMOTE CONNECTOR". According to the table, Pin 1, record output, is a variable level 100-150mV AF signal. It is, in fact, connected to the output of the audio amplifier, the same as the speaker, and the level varies with the front panel AF control.

Regarding an audio input, look at page 25 of the manual under "PHONE PATCH OPERATION". It describes how to install a phone patch input like the ones that are standard on the TS-502 and TS-820. It has you install a RCA jack in one of the unused holes in the back panel.

Hi Carl,

If you have a short jumper cable with alligator clips, recreate the VOX tripping then connect the jumper wire between the VOX Unit's "AV" terminal and chassis ground. If the VOX Unit stops tripping then I suspect the problem is loss of ground in CW mode through Mode switch wafer S3-5. Wafer S3-5 may have worn down over time causing loss of connection to ground in CW mode or it may be very dirty/corroded. Try cleaning the Mode switch wafer.

Mike,

In relation to your meter pegging (FSD) when you first switching radio on, the easy solution is either disconnect your antenna or if your using an antenna switch switch the radio to ground, this usually stops the hard FSD.

These radios are designed for approx 100w output, it could be that your radio has had QRO modification, this is where the 210v line has been change to the 300v line on the rectifier board, not a good modification at all. Depends on who does this modification, resistors on the rectifier board may have been supersized and from memory R37 on the RF board may have been supersized as well. All fairly easy to see if you removed the top and bottom covers. If you do this make sure the radio is disconnected from AC and the HV is discharged prior to poking around on any of the boards. HV provides a great service to the funeral industry.

Hi Mike,

The S meter will rise full scale when the 830 is first power on then fall back to zero (no antenna connected).

I question the "140 watts" output you claim your 830 is producing. I'll assume you have a watt meter inline between the 830's output and the antenna, or hopefully a 50 ohm dummy load, that shows 140 watts. If your watt meter shows 140 watts, what are the 830's IP and HV meter indications showing with 140 watts indicated on your watt meter and is the 140 watts indicated with a 50 ohm dummy load or an antenna connected to the 830?

The 830 has a maximum DC input power rating of 180 watts in CW mode. That is the maximum input power the final amplifier in the 830 is capable or producing. In order to achieve 140 watts output in CW mode the 830's final amplifier efficiency rating would have to be "78%" and that's simply not possible with the 830. Did you tune the transmitter into a 50 ohm dummy load using the tune up procedures listed in the operator's manual? If you did you won't see 140 watts output in CW mode unless your watt meter's calibration is off.

I meant to say the 830's S meter will rise above zero a bit then fall back to zero when no antenna is connected. Sorry about that. Too early and not enough coffee.

Mike:

What plate current are you loading to for 140 watts output?

It is OK to load to 250ma if you even can get there, but I would not as a matter of routine. Even at 250ma you should not be seeing 140watts output. Probably more like 840v x .250 = 210 x .55 = 116 watts output into non-inductive 50 ohm dummy load.

Most 830s I have seen start to fall flat much above 225ma. Have seen a couple non-modified that could attain 250ma. Had one fellow tell me he could load to 300ma and one who said he loaded his to 400ma. That is especially interesting as meter only goes to 350ma!

As Dave VK5PDL says if you are really getting out 140 watts the rig has been QRO-d or your wattmeter is not accurate. If QRO-d need to restore to factory and inspect plate choke in PA cage for signs of overheating.

Where is Ip at when you have 140 watts output?

I just settled down to do measurements on the rig, but it is behaving normally now - even FSD ALC on 28MHz (though with higher Carrier level than lower bands).

Intermittent problems are annoying!

I monitored idle current for 15 mins and didn't drop - in fact it rose slightly from 60mA to 70mA.

Maybe I should just loosen and re-tighten ground screws? Or leave till problem repeats and do measurements then.

>
> Adrian:
>
> After you adjust the resting plate current to 60ma does it stay there for some time or does it drift pretty quickly? Idle current is a function of cathode emission, control grid operating dc bias voltage, and screen grid voltage. If finals have lots of age emission can be a problem. Otherwise bias voltage and screen grid voltage must be to spec and stable.
>
> If you feel comfortable I would measure the grid bias voltage at the final board on the control grid pin of the tube socket. It is not often that the -C supply floats around, however if the bias voltage pot is dirty it can cause resting plate current to change. If you havent cleaned and exercised this pot it is good idea to do so. Easy to remove the three screws that hold the plate to side of rig to get access to pot to apply the Deoxit and canned air. Try to set it back close to original position so you dont have insufficient bias voltage and the finals run away and be destroyed when you first key rig to adjust to 60ma.
>
> As you know ALC indication is a function of RF drive voltage and dc bias offset at the control grids of your 6146 finals. Assuming that DC bias voltage is set properly then need to measure the RF drive voltage. If RF drive voltage is low suggest you try a new 12By7A Driver tube as a first step.

> >
> > Turning on the rig today the ALC was much lower than normal when I tuned up. Where I could get FSD on 7MHz with carrier control around 3 and drive peaked, I now had to wind the carrier full clockwise and only get about 3/4 full scale. Checking each band I found I was

getting no ALC on 28, and progressively higher peaked ALC going down bands to 3.5MHz (7 and 3.5 about same).
> >
> > This had happened once before and when I checked idle plate current it was about 40mA not 60mA. After setting to 60mA the ALC was fine.
> >
> > So I checked idle current and it was around 45mA. Thinking this would be bound to fix the ALC I increased to 60mA, but I still had same low ALC! Maybe it was just coincidence that last time I had to readjust idle current, the ALC was its old healthy self?
> >
> > So what could cause a sudden decrease in ALC, and complete loss of it on 10m where it was fine before post-alignment? What's obvious place to look? Could it just be finals have given up? Any reason why the idle current has dropped since last adjusted to 60mA just a few weeks ago when I last saw this problem?

Terry

If we go back before this new problem occurred,i found that i had lose crystals on the pll board causing the display to disappear when changing sidebands[re -soldered them and now working]
Loading the rig we got some arching at times.We then had a problem with low output on LSB.
Overall it was working not too bad on all bands and good output.
It had sat for a few days as i was on holidays and when i came back i worked a few stations on it and felt pretty good about getting it to that point from being DEAD.
So all connectors were in place as all was working except for some adjustments to do.
A few days later i go to load the rig,and i notice big arching going on again [on panel meter and on swr meter]so i shut it down.Awhile later i went back to turn it on and all was dead except for the front panel lamps and the fan.
I thought the transformer had shorted out,but with Mike's help that was not the case.
We then checked voltages on the audio board with Terry's help and found no output at the 12 volt post on the audio board.
I took the zener diode out and i tested it[was good],and it now has display,and relay's are working.
Why taking out the zener and reinstalling would now produce my voltage[15 volts now] at the 12 volt pin ? i have no clue why [solder joints?]
What is not working now is,no audio,just a hum on the speaker[could be going to ground],no receive,no 25kHz maker now.I do have my 60 ma's but that all.no drive,no output at all.
I guess that's why the previous owner put it on Ebay as i could see it was worked on before,because all the connectors were numbered with a marker, as i guess he had no manual.

This is a lot more involved here than my QRP gear,and i might be way over my head here.When funds allow,i need to pick up a rf watt meter and a watt meter,a new digital scope would be nice ,but too much for me to spend at this time [cruel stock market]
I did not know a rf watt meter existed until i read a post from terry and did a eBay search.
Terry has gone overboard to help me and i wish i could repay him in some way.maybe i will have to send him my mint TS830[NOT]
As i am not one to easily give me,i will keep plugging at it.

Moral of the story,don't mix your tubes,as one a B and the other a EH!

Terry
I got a Marconi signal generator and discovered all the bands were good except 40 meters.I was able to load the rig on all the other bands
So we now know the transmitter is working except for 40 meters.
That just leaves me with the receiver and so far,no audio,just that hum,and no marker.

Does the Marconi have external modulation typically 400hz or 1000hz?

If so inject it at IF Board Conn 11 Pin 1 DET. If you hear tone in speaker it tells you that Audio stage is working. Move on to testing the IF board as noted below.

If you do not hear it then inject again at Audio Board Conn 1 Pin 2 DET. If you do not hear it then inject at Conn 2 AV1. If you do not hear it inject at Conn 2 AV2. If you cannot hear it then inject at Conn 4 Pin 6 SP. Should hear it here as you are now injecting into the speaker (plus molex pin, solder connection and cabling to the headphones jack). If you can hear tone when injecting at Conn 4 Pin 6 SP and not when injecting at AV-2 then likely have a bad Q4 output device. Just follow the path from the Produce Detector output on the IF board to the Speaker.

Assuming AF stage is good now test IF board.

If you hear the 1000hz tone when you inject it at output of Product Detector on the IF board then set the Marconi for 8.830 Mhz and switch your output cable from the AF output to the RF output. I dont know what kind of output level attenuator the Marconi has. Start with a high level and inject the 8.830mhz into the IF Board RIF input at Conn 6 Pin 6. Should hear tone and should get S meter indication. If S-meter pegs turn down Marconi rf output level. Set the level for approx S9 indication.

If you get no tone when you inject 8.830mhz RIF signal then you know problem is on the IF board.

If you get good tone then you need to go back to RF board and inject there following the path from the RIF output back to the SO-239 or the other way around. I would use 14.200mhz as your test signal.

I forgot to mention as I do not know anything about your Marconi RF
sig gen it is good practice to use a .01uf blocking cap in series with the "hot" output
conductor of your test cable. Value is not critical.

400hz audio will be just fine.

Terry
The first test worked for a 400hz tone
The second test did not yield any tone or S meter indication
I also have now a BK200D also,so i tried both

I think they used that method on the Heathkit sig generators.
Thanks for that info plus many other things.

Don:

1. Are you telling me you injected audio into the Product Detector output on the IF board and you got good tone out of the speaker? Were you able to vary the level with the AF gain pot?

If so, your Audio Amp stage is working. Will have to troubleshoot lack of Side Tone later.

2. Are you telling me you injected 8.830mhz into RIF terminal on IF board Conn 6 and got no speaker tone and no S-meter indication? Are you sure you had good level at 8.830mhz? 500uv or -53dBm should give approx S9 indication. Suggest you repeat this test.

If you get no results you know there is a problem on the IF board. It is possible could be as simple as a bad connection at Conn 6.

If you turn the RF gain pot down full CCW does the S-meter drive up scale? If not, then the AGC bus may not be energized or something is pulling it down. You told me you had good 3.6vdc RF-1 voltage.

Terry K9TW

Unless you are very familiar with the design of your signal generator always good practice to use a coupling/blocking cap in series with your output lead. Dont want to damage your sig gen with high DC voltage.

Yes Terry i could vary the pot
I used my old scope to make sure i had good output on the SSG first.
I think that's the max 500uv output for the Marconi 2018
Let me recheck it all after super and get back to you

Terry
I want to make sure i am measuring the right place for the 3.6vdc,so can
you tell the board and pin number

I would be very surprised if the Marconi didnt put out 1volt or 1000mv or +13dBm. If you have the manual you need to read it to get familiar with it when you get time.

OK RF-1 is your threshold voltage for the AGC and ALC bus. It is derived from the regulated 9vdc on the Audio board. Trimmer pot VR-3 on the Audio board is used to adjust it at Conn 9 Pin 5.

Measure it there and adjust it to 3.6vdc with a DMM if you have one.

RF-1 is the power supply for the AGC bus and the AGC bus likes to have that voltage applied at the IF board. It is applied thru the RF gain pot to Conn 8 Pin 2 RFG terminal. Should have approx 3.6vdc with RF gain pot full CW and approx 2.6vdc with the RF gain pot full CCW.

At this point you still have not measured the AGC bus voltage. Just the dc power supply to it. You need a minimum of a 11meg VTVM or a 10meg DMM to measure the AGC bus voltage at Conn 15 Pin 3 on IF board.

We discussed this at least once before and I cautioned you to get on the correct pin as there is 300vdc on Pin 1 of Conn 15. I will give you the color of Pin 3 lead wire, but do not bet your life on color code conventions. Always measure to confirm. AGC bus should be the Brown wire. If your DMM is low Z input it will cause the S-meter to read up scale around 10 over S9 or higher and you will measure under 2.0vdc. With a 11meg meter should get something on order of 3.0vdc and approx S3 to S4 indication.

If Conn 6 Pin 6 RIF input is good and supplying your test 8.830mhz to Q1 amp and the AGC bus voltage is good what would you check next?

Hint: You need a Local Oscillator signal available for your 2nd rx mixer. A test point is provided to measure the frequency and the level.

Terry

Hi Mike and thank you for your comments. I just "replied" to Terry K9TW and I thank both for your comments.
Yes I loaded into Dummy antenna and , as I reported to Terry, my ip is at 230 and 775VDC shows on HV. Grid Current was set at 60ma...I still see about 138 on my wattmeter. I just received a new MFJ 870 and I did calibrate my older Para Dynamics Wattmeter to the new MFJ..... I told Terry that I am tempted to get,yet,another wattmeter to compare one meter against the others...I'm still not sure of the readings on either meter....Trust is elusive for me.
I related to Terry that I will open the hood (top and bottom) tomorrow and look for any mods. that might have been installed. I think the HV reading is close to what it should be....I keep searching for answers.
Thanks,again, Mike for your input.... I DO appreciate...

Mike.KD2DYY

Hi Terry and thanks for the comments...I did a close look at the meter on the full output that I THINK I am putting out..... My plate ip is 230 and HV is at 775 (Bias is set at 60ma).....This reading is with "send" switch on and CW.W
I am showing 140 watts BUT I cannot believe my meter. I did just buy and received an MFJ 870 meter and calibrated my older Para Dynamics wattmeter to that meter....I have this strong urge to get,yet,another meter to compare each of Three meters...Gad! Does it never end?
As I said before, I will NOT load up to the max and will hold my plate iP to 220 or less. No need to try to smoke the old 6146B's... I have yet to open the rig. I know I should and tomorrow I will and look for any and all mods. that might have been installed. I am VERY happy with what I see so far on this radio.....
Still will hold on to my old 520s... First radio I fired up with my new license in 50 years....Time does fly...
Talk with you soon......

OK if 775vdc and 230ma are accurate you would be very close to rated CW DC input power of 180 watts. Not possible to get 140 watts output at 180 watts input.

If you have some test equipment can verify output power by measuring RF voltage drop across your dummy load.

If you had a 3 diode RF probe/VTVM or O-scope could place Coaxial tee at your dummy load and measure the RF voltage at open Tee. At 100 watts output into 50 ohm dummy load you would read close to 70.7 rms volts.

E = Square root of P x R or E= Square root of 140 x 50 = 83.7rms volts measured by RF probe or 236.7 Peak to Peak volts on a Scope. 140 watts into 50 ohm load = 83.7 P-P volts.

Topic: 43531 Message: 43667

OK I think I know what's going on with my intermittent ALC problem.

To recap:

- normally I get healthy ALC, can easily get full scale on all bands bar 10m when peaking ALC with Drive, and just below full scale on 10m

- when problem arises I can still get ALC indication, but lower levels and au have to crank Carrier much higher than normal. I no longer get ALC on 10m and very low on 15m (within black ALC scale with Carrier maxed). That's with 60mA idle current.

It's heat related! ALC fine when I turn rig on from cold. It goes awry when rig has been left on for period. Am checking now to see how long before problem starts but it's within an hour or so (and temps hit in UK just now and we don't have indoor aircon, so ambient reaches 25-30C).

So where should I look for heat-related reduction of ALC? I'm going to at least make sure 12BY7A driver is firmly in base today (I replaced recently). Any other candidate parts/connectors/boards?

> >
> > Adrian:
> >
> > After you adjust the resting plate current to 60ma does it stay there for some time or does it drift pretty quickly? Idle current is a function of cathode emission, control grid operating dc bias voltage, and screen grid voltage. If finals have lots of age emission can be a problem. Otherwise bias voltage and screen grid voltage must be to spec and stable.
> >
> > If you feel comfortable I would measure the grid bias voltage at the final board on the

control grid pin of the tube socket. It is not often that the -C supply floats around, however if the bias voltage pot is dirty it can cause resting plate current to change. If you havent cleaned and exercised this pot it is good idea to do so. Easy to remove the three screws that hold the plate to side of rig to get access to pot to apply the Deoxit and canned air. Try to set it back close to original position so you dont have insufficient bias voltage and the finals run away and be destroyed when you first key rig to adjust to 60ma.
> >
> > As you know ALC indication is a function of RF drive voltage and dc bias offset at the control grids of your 6146 finals. Assuming that DC bias voltage is set properly then need to measure the RF drive voltage. If RF drive voltage is low suggest you try a new 12By7A Driver tube as a first step.

> > > Turning on the rig today the ALC was much lower than normal when I tuned up. Where I could get FSD on 7MHz with carrier control around 3 and drive peaked, I now had to wind the carrier full clockwise and only get about 3/4 full scale. Checking each band I found I was getting no ALC on 28, and progressively higher peaked ALC going down bands to 3.5MHz (7 and 3.5 about same).

To save writing to each of you that emailed me directly, thanks for the information, it appears from the replies that the audio out is an tap from the speaker, and is followed on the schematic.

I am going to look at seeing a point I can tap an audio output to the input of the mixer. I have tried to use the audio out for the ext speaker however the audio was not the best.

And I have the information from page 25 to use the phone-patch input mod, this should fix the input audio issue.

And thanks for the HiRes schematic, I do have a copy but where it is at the moment is anyone's guess.

Regards Kevin, ZL1KFM.

I would instrument the rig to find what required parameter(s) is falling off.

As you know you need proper RF drive level, good cathode emission, proper operating bias, and proper Screen grid voltage.

In RX mode not much you can monitor. You could watch 6146 Screen grid voltage and control grid cutoff bias voltages to see if they change over time. I doubt it.

Easiest first thing to eliminate is to sub all three tubes even though you did that with the driver tube. Subs can be weak of bad even if supposed NOS tubes.

Otherwise you need to measure RF drive and Operating bias voltage under key down into dummy load. You know RF drive must exceed the negative dc offset voltage. Either drive is low or bias is high. Usually it is low RF drive that causes low ALC indication.

Easy to make a quick check at finals control grids to make sure operating bias isnt drifting high.

Assuming bias is not the culprit I would run the TX level diagram using O-scope or RF millivolt meter or 3 diode RF probe and see where the drive voltage doesnt match spec ie is the level good at output of TX Mixer? If not is TIF level good? Is Local Osc level good?

Where you find RF drive low you then troubleshoot. Is it due to low CBE or DSG voltages, is it low due to low Local Osc signal level, is it low because 12BY7A Driver tube voltages are low at tube socket pins especially Screen Grid voltage and so on.

Suggest you invest in a Pamona socket for measuring Driver tube voltages with tube in the socket and under key down.

Terry K9TW

Adrian:

I forgot to mention about your plan to reseat the driver tube. You might want to leave the shield off after you do this and then power rig on and when ALC falls off during attempt to peak the drive grasp the tube with a rag or cloth to protect your fingers and apply pressure and rock the tube in its sockets. Dont push too hard.

The tube socket can have bad solder connections at the pins and at the center. Usually this would cause intermittent RF drive, but not sure about low drive.

Thanks Terry,

I am going to do the voltage checks, but the ALC when tuning is behaving OK at the moment.

But I am doing some casual operating in IOTA contest, and have now noticed a much weirder ALC problem! Maybe the symptoms point to something obvious but am baffled:

- operating SSB, when I PTT (MC50 mike)and talk, the power fluctuates as expected on external meter, but the ALC does not shift from zero on internal meter

- if I remove antenna (OFCD, showing SWR just below 2.0 at this frequency) and connect dummy load, the ALC on internal meter now follows my speech peaks

- that's with speech compressor on. If I turn compressor off, I have to turn the mike gain all the way up to get ALC needle kicking

Have no idea if this is related to previous problem, but when I tune up the ALC looks normal in Tune position.

So what could cause no ALC voltage with external antenna, but ok into dummy load?

I've only noticed this problem today, in past I could always watch the ALC deflect on SSB, and get good levels without compressor.

Thanks as always.

Adrian:

Sorry I had another thought. Need to slow down before I pull the trigger!

Another reason for the Pomona test socket adapter is that you can not only measure the key down voltages of the Driver tube. You can use a mini-grabber and connect your meter (analog meter is superior for this test as you dont have time to watch reading count up or down) to each pin and then apply pressure and rock the tube around and see if the measured voltage remains stable. For example you should see something around 4.5 to 5 volts on Pin 7 the Cathode. It should not vary or come and go as you rock the tube.

Terry

Adrian:

I know of no correlation to what is connected to your SO-239 and ALC level when modulating the rig. I would say you had a problem with your speech amp, but if that was the case should not have good ALC deflection when operating on a dummy load. Speech amp doesnt know what is at the SO-239. Have you listened on the Moni? Where do you typically run the Mic gain for normal ALC indication on voice peaks?

When you modulate the rig ALC indication results any time your modulation of the rf drive envelope causes the Control grid to go positive with respect to the control grid. So on voice peaks when the RF drive level exceeds the -60vdc or so bias voltage you will have spikes of grid current (at ua levels). This results in a reduction in the ALC bus voltage at an audio rate and causes the ALC meter to move up scale.

Different impedances and SWR at the output of the rig pi-network is no problem as long as you are able to re-adjust the Plate Tune and Plate Load capacitors to get the rig to load into what ever impedance is being presented. This network works better than most people think unless trying to load very high impedance like random length end feed or very low impedance as might be encountered in mobile vertical antenna.

What can be a problem is if the load impedance is very high due to a loose connection or with total loss of load as there will be very high voltage across the Plate Load capacitor and can cause arcing.

The 6146 tubes could see varying levels of load under key down and the plate current would be varying due to this change in load Z. Not sure how that would be seen at the Control grid. Operating bias would be same and inter electrode capacitance same. Perhaps RF negative feedback would cause changing drive? Have to give this some more thought.

I think I would measure the RF drive at 6146 control grids on dummy load as you modulate the rig. See how high it goes as you "helloo helloo helloo" or "threee threee threee" or "fivee fivee fivee" in the mic.

Then do same on the OCF dipole on a clear frquency of course.

Do you see this effect on all bands that the OCF covers?

Sorry---I made a mistake should have said any time control grid goes positive with respect to the cathode. Pretty hard to go positive with respect to itself!

Also the reason I asked about where you run the mic gain I was interested if you have noticed a change from where you use to run it. Do you now have to run it higher even when using the dummy load.

Terry

Terry this may be all my bad work.

I changed the antenna lead and all was OK. However on a meter the old one checked out OK - continuity and no short. But I did change the plug at the rig end last week for a compression type PL259, and as that was last significant thing I did it has to be suspect. I did notice that when I was swapping that connector for the dummy load, the plug and socket had got very hot.

Maybe some intermittent fault with the ground braid as the lead looks ok with meter, even when I bend the coax at the end where I changed the plug.

Now things are OK and I immediately made a few QSOs on the IOTA contest! If it recurs with replacement lead I will put rig on bench and work through your troubleshooting.

Thanks a lot and 73

Adrian:

I have been sitting here thinking about RF negative feedback and relationship to ALC indication. What difference would high SWR (I mean really high not 2:1)make on RF negative feedback? I also looked at my TS-830 notes and the schematic. Over the years I have done a lot of testing to help me understand how the radio works. Unfortunately my notebooks are not well indexed. I find in the past I have done some measurement of RF negative feedback at the RF feed-thru on the PA cage.

If you look at the PA cage you will see near the Driver tube a teflon feed-thru with a white wire on it that goes to PC board near the Driver tube. That white wire is connected to the Driver tube cathode. You can follow this on the schematic and will see where C6 3pf cap couples RF voltage from the tank circuit to the NFB terminal (where white wire from PA cage lands on the RF board).

This RF negative feedback voltage is used to improve linearity. It reduces distortion ie splatter at slight sacrifice in gain.

It can be measured with RF probe/VTVM, O-scope, or RF Millivolt meter.

In my notes I see that loaded to 100 watts out into a 50 ohm non-reactive load if I modulate with the Threee Threee or Fiveee Fiveee technique using a MC-60 with mic gain at 1200 I read from 800mv to 1000mv on voice peaks. The ALC will kick up to approx full scale of the black printed box.

If I inject 1200hz @ 7mv from audio generator into the mic line and then key it in SSB mode I can get a sustained 1000mv. The ALC kicks up to full scale and remains there.

Now what happens if you load into a reactive load? I have a 200 ohm and a 25 ohm dummy load for testing wattmeters and directional couplers, but they do not present a high enough mismatch to see any effect on the feedback voltage or the ALC indication.

My notes show that I loaded on 20 meters using my 80 meter dipole. This gives a high mismatch. At this SWR level I measured approx 3000 mv at NFB and the ALC drops way down or barely comes off zero with Mic gain still at 1200. So "high" SWR does cause greater RF negative feedback voltage and lower ALC indication.

What is going in here? What I BELIEVE is that the high SWR is shifting the PA load line. The load impedance being presented to the 6146 finals is now too high. I am now in situation of being under coupled.
This means there will be less RF current, but much higher RF voltage. The "high" SWR is causing higher PA RF voltage swing.

C6 couples this higher RF voltage back to the 12BY7A cathode and RF drive is reduced. Reduced RF drive = less ALC indication.

So my theory is that the reason you are seeing less ALC indication on the OCF Dipole than you do on your dummy load is because you have pretty high SWR on all or some of the bands

it is cut for. Perhaps something is breaking down?

Are you seeing reduced ALC indication on all the bands that the OCF is cut for or just one particular band?

If you never previously had any reduced ALC indication while using the OCF on any of the bands it is cut for then I would be concerned about feedline connection problems, or connection problems at the center insulator, or balun breaking down etc.

What does the SWR look like in CW mode on the OCF? When you built it did you record the values on all bands it was cut for so you have them for reference?

I dont have covers off my TS-830 at moment. If I get time I will repeat the measurement tests of the NFB voltage and ALC indications for different load mismatches. Just dont want to end up arcing over my Plate load capacitor. I like to learn but dont like hard lessons!

Maybe others can shed some light on this. Appreciate hearing back any SWR measurements that you make on the OCF.

Terry K9TW

OK sounds like you were presenting a high impedance to the pi-network.

Either open or high resistance short. I guess will never know for sure.

I need to wait awhile before writing these epistles!

Gt
That is fascinating Terry, and supports idea that it may have been intermittent problem with new plug I put on using compression fitting, which is never satisfactory.

I will stay alert to recurrence of problem, and try to reproduce it with the original feed line too. I am using a coax switch so I can select the old and new feed lines, but still have to run to balun to swap them over.

I was having the problem on 20m, and now it's disappeared (even putting old feedline back) I can't confirm whether affects all bands equally.

Thank you for your expertise and time.

NO, you shouldn't, not for a BIG clock! I have learned more from your "epistles" than from hours tracing the schematics....

So, you just keep right on jumping in, and I'll keep getting more good information from the Hybrid Gospel According to Terry Wagoner.

Have you considered a book? Won't be a big seller, maybe, but I would buy a copy....

Wes:

I have talked to Mike Waldrop about collaborating on a Kenwood Operating and Maintenance Handbook but as you say it would not be big seller and would have to be self published.

I have also thought about You Tube videos series, but not pursued it. I know enough about video training to know that you cannot let the video production quality detract from the message. I have seen some really poor videos both technically and video/audio quality.

I have no idea what good camera, microphone, lighting, and editing software would cost. I am sure there is wide range of quality levels and costs and many opinions on what you would need. I hate to invest money on video production equipment that I could spend on test equipment!

Besides I might be camera and mic shy!

Maybe when I hit the lottery!

Well I think you may have found problem in my antenna system from thousands of miles away Terry.

It's very wet here today and the OFCD takes odd course round corners and along fence at times, but in past on bands I use most 40 and 20 it's been around a 1.5 SWR

I just measured way high swr on all bands, and rig reluctant to tune into them in fact it was showing power up to 200W on some!

80m 6:1
40m 4:1
20m 2.4:1
15m 3:1

So either the feed SO239 got too wet as I attached coax (I had disconnected earlier as threat of storms), or there is as you say a breakdown somewhere, most likely at 4:1 balun.

Will check again when things dry out tomorrow.

Well probably should not get into long discussions about OCF dipoles.

If you flip wattmeter to reflected power and subtract reading from the 200 watts should get you back close to 100 watts.

I assume you are using a 4:1 current balun at the feed point?

If so make sure you connected the "High" voltage or "Plus" terminal to the long side of the offset. Some say makes no difference but most manufacturers mark balun polarity.

I have run 80 thru 10 meter OCFs here and found best SWR on 40 and 20. It depends on the off set dimensions you use. Really an antenna that helps if you have an analyzer to make sweeps for tuning it. Much harder to adjust the lengths just using a SWR bridge even if you make proportional cuts.

Last one I built was coax fed and I used good 4:1 current balun then a choke balun just below it to address the common mode on the shield and didnt use a tuner as the TS-830 pi-network could handle the impedance excursions presented with no problem.

If you are using a tuner might try taking it out to make sure it isnt breaking down.

I had a DX Engineering balun once that caused wattmeter to flick as if something breaking down as I loaded. Took off the cover and the O-ring gasket was not seated in the groove and was pinched and water poured out of the housing. I left cover off to let it dry and drilled couple of weep holes on bottom of the housing. All of that action belted in at 45 feet and my wife with frown on her face!

> editing software would cost.

Free. Linux. Has pro-grade software available in the OSS repositories, for nothing except the download and learning curve.

As for cameras, those are nearly cheap. Yes, you can spend a bunch-a-ton of money. No, you don't really need to. Check into the actual resolution of the mythical "average" PC screen. You're gaming for that size, and to give more than adequate resolution for one step better than that, you can use about any medium- to high- grade web camera. Use a PC for the recording cache, make it a linux box and do the editing there. 3TB disks are under $150 now, and that's for high-reliability types of disk drives.

Lighting? You can fake up lighting pretty cheaply. ONE of the halogen stand lights you find in big-box hardware stores will provide more than enough, you'll likely have to back it up a few meters to keep from washing things out. A small, hand-held spot for close-ups, and Bob's your uncle.

Camera-aversion I can't help you with.

43686. KENWOOD HYBRID USER NET (July 28th, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-28 18:36:46 UTC
From: mvgilger
Topic: 43686 Message: 43686

The Saturday's net on 40 meter was called due to smoke in the shack. Jimmy, WB2KNR was supposed to run the net, but at the last minute he had smoke coming out of his radio so by the time he got everything under control, it was late and decided not to hold the net.

The Sunday's net on 20 meter we had 8 stations checking in under ok band conditions. We had one new check-in, KF0RQ. Out of those, there was:

4running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
2 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39
April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 30, Sunday's total = 27
July 2013, Saturday's net total = 63, Sunday's total = 41 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Wishing you the absolute BEST of luck on the test.

But please, don't do what all too many do and stop with JUST knowing the test.

I don't have any clue as to your general knowledge of electronics, of course, but I have seen all too many new amateurs who only know the test bank questions, and have NO idea whatsoever about the WHY and the HOW behind them. If you're already well-taught on electronics and radio theory, then ignore the rest of this and welcome to Amateur Radio.

But if you're just beginning to find out about radio and electronics, PLEASE, ASK QUESTIONS.

Ask here, if you wish to be that 'cut above' sort of Ham, and someone (me, Terry, Mike, probably ANYONE on here), and we will point you to all kinds of FREE, web-based and book-based information on the basics of electronics and electricity.

Your browser, your local library, other Hams in your area, and this email list, will all be great resources in figuring out just why and how that radio actually does all of those nifty things that it does.

Again, best of luck. Get your ticket, but don't wait on that. Get an antenna on that 820 and start LISTENING. Besides, you can have a blast playing with various sorts of antennae, and learn even more (procedures and propagation if nothing else) while you are studying for the exams.

Im new to amateur radio and electronics in general and this radio is making me feel like im in over my head, but it was free. The radio came with no outer case or external speaker, and aside from a lil dust looks to be in good shape. when i turned on the radio all the leds came on and the display screen was on. the 10 meter bands dont show the frequency or show something different and dont adjust when i move the knob. the rest of the bands tune fine are in the right range. the main problem i am having is there is only a constant tone noise coming out of the external speakers. there is no static on any band with antenna only the tone noise. the meter does not move at all on RF or IP, on ALC it was not moving but now goes to max if i move the mode switch off tune, on comp and hv it only moves for a brief second the goes to zero and that movement is only in between switching. ive only turned it on three times, only on rec, once when i got and twice after i put the antenna in. the first time i may have heard poping noises but there were also burts of noise from the speakers when i touched the speaker wire or some of the knobs. the service manual suggests the q3(which i believe is the chip on the af avr board is defective) is bad for no noise being heard, and it suggests a great many things could be causing the meter issues. i know ill need several pieces of test equip before i can really do anything, if i can do anything. but being knew to electronics and very tight on money and info would be helpful.

43690. TS830S -Intermittant loss of RX sensitivity and TX output (and drive)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-28 23:52:13 UTC

Topic: 43690 Message: 43690

I am a newbe to the users group. I've had some on the air support from Mark IQK and he also introduced me to the users group. I have multiple TS830s - but I am relatively a new hybrid user (but have been on the air more than 40 years).

Here is the symptom: going from receive to xmit to receive I sometimes lose receive sensitivity AND I have complete loss of final drive and full loss of output. It does not happen all of the time - but when it does, it affects all bands. The only way to get back to full receive sensitivity and drive is to repeatedly try and tune the rig on 160m. The problem most often occurs when I am on 40m - but it can happen on other bands. Once it happens, all bands are affected as described above.

I suspect the problem is with RL1. I have tried "tapping" RL1 when the problem is occurring - but no change.

I have read many postings on the group - and RL1 sounds like a possible culprit. I also noticed a comment to look at connector 5 on the IF board.

Comments and suggestions would be appreciated.

Thanx a lot Wes. yea i may put off getting the general because i am new to electronics and would like to learn about it, and being unemployed i have lots of time and a need to learn a new skill. unfortunately im having some issues with the radio, which i will post about later, so even listening which is what i was dying to do will have to wait.

ive found some great textbooks in pdf form from the 50s era of electronics that im just getting started on that are pretty incredible.

any books on more modern study of electronics would be really helpful especially those that help with trouble shooting. and first i would also appreciate just a good book with an intro to electronics and circuits. its seems like a lot of what i read in the service and operating manuals and the tech exam study guide would be more understandable with a good foundation.

thanks again!

For basic electronic principles I find the older books muuuch better
than new textbooks. A lot of old Signal Corps training videos from the
'50s and '60s are on YouTube as well, these have some very good
information in them. Also, a man named Jim Williams wrote a book or two
on basic analog electronics (I don't remember the title) that is VERY
good. I can't recommend any books in particular for troubleshooting, but
I'm sure there are people here that can.

Respectfully,
Cliff White, W5CNW

Another great book for studying/learning electronics is the John T. Frye "Basic Radio Course". This book is out of print but may be found at your local library, at used book stores, at hamfest, or you can purchase the 1951 edition on CD being sold on eBay.for $9.99 (ebay #200692897318).

This sounds like classic case of bad RL-1 Aux relay but tapping on relay case does not always confirm this.

It sounds like you are not getting Q1 RF Amp bias, TX Mixer bias, and/or Driver Tube bias TR change.

Leave top cover off rig and next time it happens measure following voltages on the RF board Molex connectors:

Conn 6 MXB (Transmit Mixer bias)
-4.0vdc RX
+1.8vdc TX

Conn 8 RB1 (Q1 RF Amp bias)
+1.1vdc RX
-2.9vdc TX

Conn 8 DRB (Driver tube bias)
-44.0vdc RX
+0.40vdc TX

If you plan to keep your TS-830 I would suggest you purchase a replacement RL-1 Aux relay while NOS subs are still available.

Ordinarily do not recommend replacing parts that are not proven to be bad, but in this case replacing this relay will ensure many years of trouble free operation. Cleaning the contacts of this relay does not prove to be very effective or a long lived fix.

>
> Here is the symptom: going from receive to xmit to receive I sometimes lose receive sensitivity AND I have complete loss of final drive and full loss of output. It does not happen all of the time - but when it does, it affects all bands. The only way to get back to full receive sensitivity and drive is to repeatedly try and tune the rig on 160m. The problem most often occurs when I am on 40m - but it can happen on other bands. Once it happens, all bands are affected as described above.

I was able to vary the voltage at RF-1 from 1v to 3.6 volts.
The AGC bus voltage was 340 volts.
I could not hear or see any signal when i injected a 8.830 signal.
My Marconi 2018 max is 500 mv,so that should have been enough signal i
would think to hear it.

The hum on the speaker is constant and i can not vary it,,like something
shorting to ground.If i remove Con 4 on the AF board the hum is gone.
I do now also have a BK200D which has a built in crystal calibrator
,,1MHz and 100 KHz
Still no audio,no marker signal,and no side tone.

Topic: 43556 Message: 43698

Don:

1. I told you to measure voltage at RFG on IF board as you varied the RF gain pot is that what you did? Not RF-1.

2. If you measured 340vdc then you did exactly as I cautioned you not to do? You were to measure the AGC bus voltage and not the 300 supply.

3. Why do you keep messing with the Audio board and unplugging connectors? You proved the Audio pre-amp and output were good by injecting audio from your RF sig gens and could hear the tone and vary its level in the speaker with the AF gain control.

I thought we had moved on to signal injection/signal tracing on the IF board? I am confused?

Our next goal was to confirm that the AGC bus was powered and that you can vary S-meter from 0 to FSD with the RF gain pot so that the IF amp mosfets have required gate 2 dc control voltage. No point in injecting 8.830mhz RIF signal if the IF amps are turned off.

4. Next step is to continue injecting 8.830mhz signal at RIF terminal and go down the signal path and look for presence with O-scope, RF Probe/VTVM/DMM. First easy spot is IFo1 either at IF board or at rear panel connector. Next is at filter switching diodes after Noise Blanker gate and so on.....until you find where signal is lost.

5. I previously mentioned assuming that you have good AGC bus voltage that you could skip ahead and validate that you have required LO for the RX 2nd Mixer. Was hoping you would review schematic and identify TP-1 as the test point to confirm you have good 8.375mhz VBT oscillator signal level (1.0rms or 2.8 P-P). 8.830mhz - 8.375mhz = 455khz. Absent 2nd Mixer LO there will be no 455khz IF and no output. Not common failure, but an easy quick check.

NOT RF-1 SHOULD BE RFG????
>
The AGC bus voltage was 340 volts. NO NO NO THIS IS 300BUS AND NOT AGC BUS??? WHAT IS THE AGC BUS VOLTAGE AT PIN 3????
> I could not hear or see any signal when i injected a 8.830 signal.
> My Marconi 2018 max is 500 mv,so that should have been enough signal i> would think to hear it.
YOU CANT INJECT AT RIF AND IF CANT HEAR OR SEE CALL IT QUITS. NEED TO PROGRESS DOWN THE RIF SIGNAL PATH TO FIND WHERE LOSING THE SIGNAL???
>
> The hum on the speaker is constant and i can not vary it,,like something
> shorting to ground.If i remove Con 4 on the AF board the hum is gone.

WHY ARE YOU DOING THIS???WHAT HAS THIS TO DO WITH SIGNAL INJECTION SIGNAL TRACING ON THE IF BOARD??? I THOUGHT YOU PROVED THAT THE AUDIO AMP STAGE WAS WORKING????
>

I do now also have a BK200D which has a built in crystal calibrator

Don:

Please do this one AGC bus voltage measurement for me.

1. Conn 15 Pin 3 AGC at IF board. Caution: 340vdc at Pin 1
2. Measure the dc voltage at Pin 3 with a 10 meg DMM or 11 meg VTVM
3. Vary the RF gain pot from full CW to full CCW
4. Should see approx 3.0vdc at full CW or wide open
5. Should see approx 0.70vdc at full CWW or full off position

When you report this we can then take 1 or 2 sentence steps going forward.

Terry K9TW

43702. TS-820S Display problem even after working on DG-1

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-29 12:18:12 UTC
From: w3drk
Topic: 43702 Message: 43702

So I have a TS-820S which I've been slowing bringing back from the dead. Everything works perfectly now but I have pressing issue I'm unable to solve.

The display works fine on 14 MHz through 29.5 MHz, but on any band below 14 MHz the display goes crazy. For example, on 40 meters the display will show 8.xxx with xxx being a random number that is constantly changing.

I re-soldered EVERY connection on the digital counter board, put wire through all the vias and also soldered the chip pins where there were solder pads on the component side of the board too. On the mixer board I re-soldered all the chip pins on both sides but didn't bother with the other components because the solder joints look decent.

I've cleaned the mating pins multiple times with deoxit as well as regular contact cleaner so the pins and sockets are sparkling clean but still no joy.

At this point I think it's time to move onto more detailed trouble shooting. I remember reading there was a way to check for proper signals into the mixer board and a clean signal out of the mixer into the counter. Does anyone have a link or a description on what those steps would be?

Thanks!!

43703. 520s LOW Rf output.....

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-29 14:11:31 UTC
From: Mike McHugh
Topic: 43703 Message: 43703

Help.....
I was going to fire up my stand by 520s last night(been awhile and wanted to make sure it was ok) and while tuning it I heard a spark on the left side of the rig....I wasn't sure if it was within or outside the 520 cabinet. Geez!
I did the smell test and all withing my sniffing detected nothing. I tried to continue on my tune up and all was normal EXCEPT very low rf output through my external wattmeter...(yes ,I verified the wattmeter with my other rig...830s). This morning I pulled the hood(s) on the 520 and looked around for any evidence of scorching or smells at all locations. Nothing. It may,well, have been external. Hope so. I did change out the finals and Saw no change. I get about 10-15 watts output...I do have the normal ip of 220 and FDM on drive.Grid is at 60 ma..My HV is at 750vdc. All looks good but very little output... I was lead to believe that the older Kenwoods do not have a "fold back" circuitry. True? Guess I need one of the members to get me pointed in the right direction. I am limited in my testing gear but have several Multimeters and a scope.If need be,I could come up with more testing apparatus...Just need suggestions as to where start troubleshooting.

Thanks Ahead of time.
Mike KD2DYY

43704. Re: new member intro

Topic: 43687 Message: 43704

Hey, Dan,

I've been a member of this group for only a couple of months, but these guys are extremely well versed in how the 820s works. I studied for about a month and got my Tech and almost passed the General that same day even though I didn't really study for it.

I bought the ARRL Tech Study Guide off of Amazon and at the same time downloaded the PDF for both the Tech and General guides from Dan Romanchik's site:

http://www.kb6nu.com/tech-manual/

I read the ARRL guide through completely twice to understand the concepts better and then started with Dan's guides to be sure I understood even better.

I agree with the advice the guys are giving you here - be sure to understand what the questions and answers mean instead of just rote memorizing. Everything builds on each other, and finding guys locally in ham groups helps a lot more to get hands on to see the concepts in action.

Hopefully by Thanksgiving I'll be comfortable enough to take the Extra exam.

After reading posts here and asking some questions, I've been able to find out so much on how to work on my 820. It will shock the crap out of you, though, so be careful if you mess around anywhere close to the back right where the tubes and high voltage are. If you don't know much about these radios, you will have a very rude awakening. Thankfully I haven't had any shocks yet, but I try to take that healthy fear to heart when working on mine.

I'm sure after enough study you'll do great on the exams. Here are some practice questions that you can take online:

http://www.qrz.com/hamtest/

Between QRZ.com, eHam.net and arrl.org, those should keep you busy finding out all kinds of new concepts.

If you need more info about licensing and studying, feel free to email me separately from this group so we don't tie up the message board. I'm not an expert on the radios like these guys are, but I'll help in any way I can. Follow their advice when they give it, and if you have any trouble understanding what they're talking about, find a local Elmer to help you out. The local Elmer is invaluable to you starting out - I have a couple of guys that are really helping me here.

Look forward to hearing you!

Are you 100% sure that you have good Audio stage or do you need to repeat testing of it? No point in going on to the IF board until certain Audio stage is working.

One other thing you can do is to park one of your good TS-830s next to this broken one and take top cover off and you can jumper between the two rigs. For example you could couple IF Board Conn 11 DET output from the good rig to Conn 1 DET input on the bad rigs Audio board. Essentially would be using the good rig as a sig gen and/or sig detector.

If we are going forward with RF signal generator signal injection on the IF board do the following:

1. At each test point vary the rf output level from your sig gen while you are monitoring the signal at each test point to make sure that you are really seeing the test signal. You can also turn the modulation on and set it high (75 to 100%) to aid you in recognizing your test signal.

2. Also measure in CW mode and SSB mode at each test point because we will be dealing with filter switching diodes as we progress.

OK next place to look would be at the output of the Noise Blanker Gate and the input to the Xtal filter. Get on Diode D41 anode or D6 cathode.

If good signal there next place will be the output of the Xtal filter at the cathode of D7 (D7 and D42 are nearly touching each other). Level here will be lower due to filter insertion loss.

Once you get to the output of 2nd RX Mixer Q2/Q3 you will need to make sure the Sig gen internal modulation is turned on so you can measure the now 455khz test signal. If you do not do that the 8.375mhz LO leak thru at output of the mixer will fool you. Look at the schematic and see which switching diodes you can get on at the input of CF2. Look at installed config and see if anode or cathode is available to you on top side of board.

Don:

There is one other method you can use if you are 100% certain Audio is working. You can just inject RF along the signal path and listen for a response from the speaker. Must make sure you have AF gain turned up.

You will use modulated 8.830mhz and inject at RIF and then IF01 and then D5,D6,D41 and then D7,D10, D42. When you move RF sig gen output probe to the output of RX Mixer (D11,D12,D34) you will need to change the RF Sig Gen output frequency from 8.830mhz to 455khz.

You just keep injecting until you get good signal out the speaker. You then know the fault is between that point and the last previous point.

This may be easier for you?

Terry
OK i will start at at the beginning again.The reason i was looking at the AF board as i thought maybe i had did a solder bridge when i reinstalled the diode.
First i need to reorganize all the printouts i have plus i have test equipment and tools all over the place.
My other TS-830's are running good and i don't want to screw any of them up,so i will pass on that for now
I am expecting to get a parts rig in the next month that does not have a lot wrong with it,so i could use it.

I'll be back

Mike,

"Grid is at 60ma"??
Where do you see "60ma of grid current" in your 520? None of the hybrids have the ability to display "grid current" on the meter.

"My HV is at y750VDC"???
Is that in SSB or CW with transmitter keyed, MIC and/or CAR gain control(s) set FULLY CCW and meter switch set to HV?
Is that with 220ma IP current displayed?
You need to specify which one.

None of the Kenwood hybrids have an SWR "Fold Back" circuit.

You said the 520 is producing 10 to 15 watts output. Is that into a 50 ohm dummy load and on "ALL" bands or just one band?

You need to explain further plus try ALL bands.

Ok John ,you are quite correct that the "bias control" (on the right side if rig)does,indeed, set the idling 60 ma of plate current....I merely wanted to call this adjustment out to you as I did adjust this to specs.to insure that I have followed the proper tune up conditions to get the 100 plus watts out of the rig....So we did establish this point..... Have you or one of the members formed any troubleshooting steps I can start on to help correct my issue?????

Thanks, Mike KD2DYY

Ok Mike
I will take your questions one at a time...First it is 60ma plate idling current (per tune up procedures)
750VDC is with "send" key up..
In "tune position" drive is adjusted to full meter deflection without pegging(Using the "car" control to bring it just to full scale with drive control,Not pegging the meter)
The 220 ma ip is with meter switch turned to HV position...
I am loading into 50 ohm dummy.
On all bands that I operate 80M/40m/and 20M, I am only getting the 10-15 watt output.
Just a point. I have been using the 520s for some time and have always had good 100 plus watts out using the "Book" tune up procedures... Unless I'm mistaken I am using the right tune up procedures.
I ask, again, what are your thoughts.....

Thanks,Mike,KD2DYY

Topic: 43689 Message: 43714

Hi Dan,
Please don't touch any more 'wires'. These 900Vdc rigs can kill you.
"All the led's are lit" - FUNCTION switch is incorrectly set. See below.
Don't worry about the AF board yet.

With the rig disconnected, read the Operating Manual. If you don't have one, ask us.

Looking at the back of the rig :
- check the fuse for continuity and correct rating
- find the SG slide switch below the fan. Slide it down and leave it there.
- find the EXT VFO socket upper far right. A plug or shorting pin should be fitted.
- verify that the cooling fan turns when the POWER ON switch is briefly switched on.

Looking at the front with power connected but POWER switch off:
- push and release the RF ATT button near the band switch.
- push and release the RIT button near the band switch
- turn BAND switch to 14
- switch the row of 5 black switches to down position
- set MODE switch to USB.
- push and release the DH button out located below the METER switch.
- turn DRIVE knob to point staight up.
- turn RF GAIN full right
- turn AF GAIN to 3 o'clock
- verify HEATER switch is off
- turn FUNCTION switch to 25kHz position
- verify that IF SHIFT is centered
- verify that only the VFO led is lit when the POWER ON switch is briefly switched on.
- turn the tuning knob to 14.0MHz
- switch POWER on and rock the tuning knob around 14.0MHz.
Listen for whistles and watch for S-meter movement.
- switch off.

Report back on exceptions to the above.

Transformer saver :
- before switching on an unknown rig, an incandecent mains lamp can be wired in series with the rig. A continuously bright lamp indicates heavy current, a dimming lamp is good.

Terry
Starting at the beginning.
Lets go back to the audio AF board to make sure all is OK.

Now when you told me to inject a tone[400hz] at Conn 11 pin 1,[IF board]i did not do the rest of the test on the audio board if a tone was present.
On conn11 pin1,i get a tone only if i turned it up at least 3/4 of the way.

Decided to test the Af board to see what i could find.
Conn1 pin 2 DET----------very week
Conn 2 Av2----------very good tone
Conn 2 Av1----------have to turn it up to 3/4 to hear a tone
Conn4 pin-6 SP----------can hardly hear it.
Using the RF method,nothing is heard.
On the AF board 12 volt out pin,was 12.6 volts and now showing 14,5 volts but not concerned at this time.

Will do the next steps tomorrow

Don/Ve2ud

From: Terry Wagoner
Topic: 43700 Message: 43716

Don :

Should not show 14 vdc on the 12 volt regulator post. Something wrong with your series pass regulator. What is your 9VDC regulated doing?

If these voltages are not to spec need to stop and repair regulated supply before going any further.

Print this note so can come back to testing the Audio amp stage.

Conn 11 Pin 1 is on the IF board. It is the audio output from the Product Detector. A red miniature coax cable connects Pin 1 DET (hot) and Pin 2 (shield braid)to Conn 1 Pins 1 and 2 on the Audio board. There is a transposition. Pin 1 is the shield braid and Pin 2 is the hot or audio signal.

The schematic is wrong at Conn 11. It shows Pin 2 just going to Chassis ground. This is not correct. The red coax shield braid is connected to Pin 2 G.

At the AF board the shield goes to Pin 1 GND and not Pin 2. Pin 2 is DET. This is important as the shield braid is needed to provide the ground return for audio pre-amp transistors Q2 and Q3. If you lose this shield braid you will have no audio output. Losing it means bad solder connection at molex pin at either connector, cracked trace to pad, or bad crimp to the braid.

So at the IF board connect your signal generator hot or audio test lead to Conn 11 Pin 1 DET through about a .47uf cap and connect the sig gen grd lead to Pin 2. Can use couple of straight pins pushed down inside the molex plug body to make good contact.

With AF gain at 3/4 and 10MV of audio injected volume will be loud. With 20mv of audio injected it will be very loud. Loud of course subjective.

If you have no audio it is possible that you have lost the return thru the mini coax braid path.

You can measure the resistance from the shield braid to chassis ground at each end of the mini coax at respective molex connectors. With each plug seated it should read approx 0.3 ohm or better.

You will need to have rig on its side. Suggest you take a piece of cardboard (8 1/2 x 11) and lean it to cover the HV filter caps to prevent accidently swinging a test lead into the 900vdc.

Lets not move on until we have good "loud" audio out the speaker by injecting audio at Conn 11 on the IF board.

Mike,

You said:

"The 220 ma ip is with meter switch turned to HV position..."

Setting the meter switch to "HV" (High Voltage) will not indicate final amplifier cathode current (IP meter switch setting). The "HV" meter switch setting displays the Rectifier Unit's high voltage (800 terminal on the Rectifier Unit) applied to the final tube plate caps. All the meter switch settings are disabled in standby (Receive).

You said:

"In "tune position" drive is adjusted to full meter deflection without pegging(Using the "car" control to bring it just to full scale with drive control,Not pegging the meter)"

I don't understand why, after you adjust the DRIVE control for a peak meter pointer indication, that you further adjust the CAR control for a further peak indication (not pegging the meter)? You do not have to do that. All that's necessary is to set the Mode switch to TUNE, set the DRIVE control to 12 o'clock, set the meter to ALC, set the CAR control to 9 o'clock, then key the transmitter and adjust the DRIVE control for a peak meter "pointer" indication, no meter scale are used. If the meter pointer pegs fully to the right, adjust the CAR control CCW for a meter pointer indication of 12 o'clock then continue adjusting the DRIVE control for peak meter pointer indication. Once the peak is achieve, you do not adjust the CAR control for a higher meter pointer indication. You achieve nothing, by doing that.

If the 750VDC and 220ma are correct, those figures indicate 165 watt DC input. The final amplifier in the 520 operates in Class AB1 which has an efficiency percentage of 55% so that would equate to approximately 90.75 watts output at the antenna connector (750 x .220 x .55 = 90.75). If the tune up is procedures you are using results in normal indication on the 520's meter switch settings as stated in the manual then I suspect your watt meter may be at fault.

thanks for the reply dave. id did have an operating manual but i guess i missed the sg switch settings, mine was on, however when i turned it off i still heard nothing coming for the external speaker other then this constant pitched tone. the meter in alc went about two thirds up instead of to max as it was, but still no meter movement in ip, rf, comp, or hv.

Will read that over very carefully first.I don't know what has changed
as i did get the 12.6 volts after i reinstalled the zener,
but as you pointed out,something wrong with pass resistor
I think the 9vdc was fine,but will recheck it too.
Yes it does not take much to have a lead swing or fall were you don't
want it too.
I need to order that large schematic from ken,as it's a pain to keep
blowing it up on the computer
to 400% to see it well,and even then you only get to see a small part of it.
Thanks for your time

Daniel,

Do not operate the TS-820, which includes not plugging the TS-820 into the wall outlet, until you obtain the top and bottom covers. Operating the 820 without the top and bottom covers is dangerous!

I also recommend you thoroughly read/study the TS-820 operator's manual first. You should have a thorough understanding of what each control is for, how to use the control(s), and never operate the TS-820 without the top and bottom covers installed. Once you have experience in troubleshooting you will learn how to safely operate the TS-820 with the covers off but until you gain that experience, do not take the covers off without an experienced person/ham by your side. As one response said and I agree, there are voltages in the TS-820 that can easily KILL YOU!!!

The rear panel "SG" switch must be set to "ON" for normal transmit operation. The "SG" switch has nothing to do with nor does it have any affect on receive.

The meter switch settings are disabled in receive, activated ONLY in transmit. Each meter switch setting is explained in the operators manual. Normal operation the "FUNCTION" switch MUST be set to "VFO".

Dan,

It is essential for you to read the Operating Manual.
Go to Gordons website and download it for free.

The SG switch setting is to protect the finals and prevent inadvertent Tx.
It does not affect receive.

Does the "constant pitched tone" respond to the AF GAIN control?
Is it a 'pure tone' or noisy?
If you switch FUNCTION to VFO position does the tone stop or change?

In recive, the meter only functions as an S-meter. The METER switch is not used in Rx.
ALC, IP, RF COMP and HV are for Tx.

Is just the VFO led lit when the POWER ON switch is briefly switched on?

***** Did you set the rig as advised? ****

Yes I would get Kens big schematic. I use one all the time and have one in reserve. Much easier to use.

Question: When you are injecting 400hz audio into Conn 11 on IF board do you have Conn 11 plugged in and Conn 1 on Audio board plugged in? They must both be plugged in.

If you are uncertain of audio level from your Marconi suggest that you use the BK200D for your 400hz audio test signal. Connect test leads to Red/Blk jacks, set selector switch to 400hz out, place meter selector to % modulation, increase Modulation level pot for maximum on the meter (never need this level but start here).

If you are uncertain if it is working you can look at the 400hz level on your O-scope. I am former owner of this sig gen and as I recall you can get over a volt of audio out of it at the 50% mod level.

You could also inject it into the mic/line input on your laptop to confirm it is working.

You dont need more than 10-20mv rms or 56mv P-P to get very loud tone from your TS-830. So you could set the P-P level around 100mv on the scope and then connect to Conn 11 at IF board and back it down from there.

Terry

I checked the voltages around the Q34 area AF board and found that they
were too high,for my liking.
So i removed Q34 and it is bad.The 1000uf cap was reading about 780uf,so
i should change those caps also as you suggested way back.
The 9 volt side is fine.
So i need a source or maybe someone in the group that has one.
Don't know if this will solve the problem totally ,.but it's a good start.

Dan, (Mike and Gordon)
Leave the SG switch off. You won't be transmitting.
The originator of this group called the SG switch "the grandkid's switch".

Be aware that those high voltages still exist on the rig with the SG off, during receive and even after switching mains off and disconnecting from mains.
As Mike indicated, if you 'tinker' with this rig, you won't need our help...

Dan, forgive the question but how old are you and how much technical knowledge do you have?

Gordon, would you kindly help Dan to download the Operating Manual. Thanks.

You can find 2SA473Y pulls and new ones on Ebay or use a NTE 153 sub also available on Ebay for around $3.00.

im 28 and while i did know capacitors hold a charge and this a an HV rig, other then that my electronics knowledge is very limited. im reading a pretty good and watching an online class about electronics as we speak but i imagine it will be a few weeks or months before im comfortable doing anything beside soldering something simple and easy to get to(which appears non existent on this rig). i do have the operating manual a did follow the procedures on setting up for recieve. after i heard no noise other then this constant tone i started reading the service manual. i have attempted nothing on send. and thats where we (and sadly the radio) sit today.

Before anyone wastes their time responding to this post, I wanted to follow-up that managed to solve the problem.

I documented the repair here, but long story short it was a bad choke on the DG-1 Mixer board. Hopefully this info can help some others struggling with their DG-1.

The sole purpose of the rear panel "SG" switch is to control the "Polarity" of the DC voltage applied to the final tube screens, nothing more.

Setting the SG switch to OFF results in a "Negative" voltage applied to the screens.

Setting the SG switch to ON results in a "Positive" voltage to the final tube screens.

The "normal" setting of the SG switch is "ON".

Applying a negative voltage to the final tube screens will BLOCK the flow of current t0 the final tube plates. This results in an IP meter indication of "zero" in transmit. Do NOT confuse this with blown cathode resistors. Blown cathode resistors will result in zero ALC and zero IP current meter indications on ALL bands.

If the final tube cathode resistors are okay, placing the SG switch in the OFF position will result in zero IP current indication but it will NOT result in zero peak ALC indication in TUNE mode adjusting the DRIVE control! Why? Because the "GRID" sits between the cathode and the screen and plate. Electrons will still flow from the tube's cathode to the grid with the SG switch set to OFF but electrons will be BLOCKED from reaching the tube's plate by the "negative field" surrounding the tube's screen. The tube's screen is between the "grid" and the "plate".

To understand what this all means and how this all works take the time and study vacuum tube theory in the ARRL handbooks if you plan on servicing vacuum tube circuits. One should have a solid understanding of what polarity an electrons has and how electrons react to negative and positive potentials.

I forgot to include:

Although the SG switch is set to OFF when neutralizing the final amplifier, the switch itself has nothing to do with neutralization of the final amplifier nor is the switch part of the final amplifier's Neutralization circuit. The switch simply controls the "Polarity" of the DC voltage applied to the final tube screens, nothing more.

OK Dan. Thanks for the personal info.

Please answer my previous questions :
-Does the "constant pitched tone" respond to the AF or RF GAIN controls?
-Is it a 'pure tone' or noisy?
-If you switch FUNCTION to VFO position does the tone stop or change?
-Is just the VFO led lit?

it responds only to the AF gain (tone gets louder as af gain is increased)

pure tone like a keyboard key held done.

changing function switch does nothing to the tone.

and yes only the vfo led is lit when switch is set to vfo

sorry about not answering the first time

Terry
Do you have any preference's on buying the original ones or are the
NTE153 just as good.
The NTE ones are cheaper and less shipping charges,and i will get two to
be safe.
When i reinstalled that zener the voltages were the correct,so something
took it out as that's why we moved on to your other steps.
Was that a mistake on the schematic [had to be]at post 14A it says
17.6 ac volts,as you stated VDC and that's what i measure was DC volts.
Chokes block AC.

On the good side you will get a rest from me until i get the
replacements in hi hi
Have lots of good reading to do in the mean time on all that valuable
information you have given me.

NTE153 is fine. Schematic is wrong. Output of the C-L-C pi-filter is DC.

Pretty sure I gave you a resistance measurement to make from the 12vdc post to chassis ground to make sure you had no fault on it.

I like to know the root cause of failures, but sometimes no obvious reasons why can be determined. Just gets tired.

I know you have voiced reluctance to use your other TS-830 rigs in troubleshooting, but it can be invaluable aid in determining what "normal" design operational parameters are so you can compare with the problem rig. Can also measure and record currents, voltages, resistance, waveforms etc in notebooks or mark up the large schematic so you dont have to constantly remove covers or leave covers off. It helps me all the time. I have some of the basic stuff in the file cabinet between my ears, but most of time I refer to my big schematic and notebooks developed over the years.

Topic: 43689 Message: 43735

Hi Mike:

I dont have a problem with recommendation to a newly licensed and new Hybrid owner to leave the SG switch off for time being. Not designed specifically for operator error, but in this case inadvertent keying of rig with Heaters on, CW mode, and Car Pot turned up could result in loss of finals and/or plate choke or ???

Kenwood provided the SG switch for two purposes: (See TS-820 Operating Instruction Manual Maintenance Section 6)

1. To allow "cold" neutralization without having to lift the screen grid lead and anode leads and having to worry about securing the hot ends of those leads if you did the lifting at the tubes.

2. To allow Transmitter alignment ie peaking of the coil pack Drive Coils without RF output.

3. I use it also for load testing the Drive tube stage, but Kenwood makes no mention of this in the manuals.

4. As noted above it can prevent inadvertent transmit which could damage the rig. I often see Hybrid pictures on Ebay that show the heaters on and the rig flipped to send and it makes me cringe!

> Setting the SG switch to OFF results in a "Negative" voltage applied to the screens.
>
> Setting the SG switch to ON results in a "Positive" voltage to the final tube screens.
>
> The "normal" setting of the SG switch is "ON".
>
> Applying a negative voltage to the final tube screens will BLOCK the flow of current t0 the final tube plates. This results in an IP meter indication of "zero" in transmit. Do NOT confuse this with blown cathode resistors. Blown cathode resistors will result in zero ALC and zero IP current meter indications on ALL bands.
>
> If the final tube cathode resistors are okay, placing the SG switch in the OFF position will result in zero IP current indication but it will NOT result in zero peak ALC indication in TUNE mode adjusting the DRIVE control! Why? Because the "GRID" sits between the cathode and the screen and plate. Electrons will still flow from the tube's cathode to the grid with the SG switch set to OFF but electrons will be BLOCKED from reaching the

tube's plate by the "negative field" surrounding the tube's screen. The tube's screen is between the "grid" and the "plate".
>
> To understand what this all means and how this all works take the time and study vacuum tube theory in the ARRL handbooks if you plan on servicing vacuum tube circuits. One should have a solid understanding of what polarity an electrons has and how electrons react to negative and positive potentials.

Terry
I don't remember if you gave the resistance test,for it,but now that i
have time to check all my notes i will look for it.
I checked with the fellow who is selling me a TS830 with minor problems
to see if he will be shipping it soon,so i will use that one for
troubleshooting,after we troubleshoot that one hi hi.
I have that cheap ESR Chinese meter from Ebay, so should i remove the
caps in that area and check them before i order the pnp's as that seller
carries a wide selection of other electronic parts

http://www.ebay.com/itm/NTE-NTE153-BIPOLAR-TRANSISTOR-PNP-90V-TO-220-NEW-Qty-1-/140878446238?pt=LH_DefaultDomain_0&hash=

Hi Daniel,

We were just checking setup and a few functions of receive.
Sometimes, simple setup errors cause faults. In your case it seems to be more than that.
Sorry I can't offer any solution.

When I got my 820s years ago, it also wasn't working. I received help from my local radio club and repaired it. It's been good ever since and has been maintained via this group.

The experts may be able to help you (along with your local club?)
Over to Mike, Terry, Gordon, ...

Bonne chance

eliminating non possibilities is still very helpful. despite having the manual i was still nervous when i flipped the switched the first time(now i wish i had waited till i joined a club and got some face to face before i did) and i appreciate all your responses dave, they also opened up an interesting discussion on the sg switch. we have at least three clubs i know of in the pinellas county (gulf side near tampa) and im excited to get involved with them as well.

OK I likewise have digital LCR bridge and the Anatek Blue ESR meter.

Without original factory data sheets dont know how you know what ESR is too high for these? You could use a rule of thumb plus ESR meter use practical experience to set some acceptance criteria for these electrolytics, but with the board folded over on a 30 plus year old rig with failure of the series pass transistor I would install new filter caps and be done for remainder of the rigs life. Certainly for remainder of my life!

Goes against the "if not broke dont fix it" and I am not in favor of wholesale recap of the electrolytics in these rigs, but I think these caps are good candidates for replacement if a related failure presents the opportunity. I would ESR and Bridge them and record the as found readings same as I would for the new ones.

Just my thoughts.

Before anyone wastes their time responding to this post, I wanted to follow-up that managed to solve the problem.

I documented the repair here, but long story short it was a bad choke on the DG-1 Mixer board. Hopefully this info can help some others struggling with their DG-1.

Daniel:

You might try contacting Danny Cannon KI4AX at Hudson Florida. Not too sure how close he is to you? He is experienced TS520 and TS820 owner. He can help you learn how to load the rig.

Mike W5RKL gave you good advice about cracking the books and learning how a vacuum tube works especially a tetrode (tube with Screen Grid). That knowledge wont come over nite and of course not realistic to expect you to wait to fire up the rig until you have that fundamental understanding. An expectation not to plug it in until you have acquired and read at minimum the Operating manual is a reasonable expectation and wise counsel.

I would say that 95% of all newly licensed Hybrid owners almost immediately fire up their new Ebay or Hamfest hybrid when they get it home and most with no copy of the Operating Manual and the Service Manual.

For that reason Daves suggestion to leave the SG switch turned off until you have read tuning/loading instructions is a legitimate use for the switch. Not a Kenwood design purpose, but a good safety valve.

These rigs are pretty robust. Mike and several others here are experienced with operation and repair of TS-820 rigs. One or more of them should be able to help you with your rig. Of course you need to know that next thing you will hear about is the minimum level of required test equipment to keep these rigs on the air. A modest investment that will include a dummy load most likely as your first acquisition. Either home brew or purchased.

Good Luck
Terry K9TW

Daniel:

Dave gave you a very detailed list of how to pre-set all the controls for receive mode essentially out of the manual. I have just couple of questions and will back away and let Mike, Joe and others work with you. If anyone needs help I will try to lend whatever support I can.

1. How did you connect the remote speaker or speakers?

2. You report ALC indication (S-meter) in receive mode is 2/3 full scale. Is the RF gain pot full CW position?

3. What happens when you turn the AGC off?

i connected to external speakers through the speaker jack in the rear, there is no internal speaker but the wire and plug is still there.

yes the rf gain pot is turned fully clockwise

nothing changes when i switch the AGC to off.

thanks for the reply's terry

Dan:

Given that the rig has no outer case, I would expect that the TR relay on the bottom has fallen out of its socket, which will cause all sorts of problems. That happens with my TS-820S every time I take the case off. Set the rig on its right side and take a look at the relay located in more or less the center of the bottom.

The tone you describe I also experienced when I was first checking out my problem-plagued TS-820S. I think you are hearing the sidetone in CW transmit mode. If that is the case you also have probably burned out the usual suspect resistors, which is are no big deal to repair.

Where are you at in Florida? I am on the central east coast.

Daniel:

OK Strongest recommendation I can give you is one you probably wont like and that is to get local in person help if at all possible. Perhaps from a club? As I mentioned give Danny KI4AX an email if Hudson is close to you. Lots of hams in Tampa/St. Pete area.

There is exposed 900vdc and 300vdc with enough ampacity to kill you in this radio.

It is hard enough to come in completely cold and get a fully functional KW Hybrid operating properly. When you have one that has these kinds of problems it is really helpful if you get someone with experience who can help you. Far better to be able to observe as well as reading.

Hello all. New guy here. My name is Matt, callsign KF5LCH. I recently picked up my first hybrid Kenwood rig, a TS820S. It's in mint condition inside & out, very clean. I am still relatively new to Amateur Radio, so I consider it a learning experience. I want to learn the hobby. I'm currently being elmered by a couple of great old school hams at the club & I'm studying for the extra ticket. I'm also doing my best to learn code. I have also enrolled at the local vo-tech, taking intro to electronics. Please excuse my ignorance. I have been a locomotive engineer for the last 12 years, so electronics is a little out of my league. I have been using all Kenwood gear since I got my ticket & prefer using it over other equipment. The first time I heard a hybrid on the other end was at Field Day last year with the local club. I had been working a Kenwood TS480 all day, when I cam across a station with the BEST sounding audio I have yet to hear. Every contact was asking him about his rig. He advised it was a Kenwood TS820 he bought new in 1979. Man did it sound good. Anyways, I'm looking forward to meeting you guys & talking about these rigs. Thanks for having me.

OK I know you are excited and anxious to get this rig going. Just take it one step at a time. It is possible you may need cathode meter shunt resistors later when you attempt to load the rig, but dont worry about that at this time. As you know Ken K4EAA is close to you so good resource for parts you may need.

I also note you joined QRZ forum. That is OK just be careful with the Kenwood Hybrid specific advice you get there. Need to evaluate it same as any forum. Problem over there is many of the folks are not and have never been Kenwood hybrid owners and will give you general boat anchor answers that seldom address your specific problem and sometimes are just flat wrong.

If you cannot get local help come back here and one or more of us will take you step by step thru troubleshooting your rig.

I have 10 years practical hands on experience and sometimes I can put my finger on a problem literally in minutes and in other cases where a radio has been abused, modified, hacked it can take me a week or two to figure out what is wrong.

Regards the yellow Speaker wire in the rig wrap some tape around the two bare plugs so not shorting them to anything in the rig.

Lastly, when you do get some help you may want to carefully unplug all the white Molex connector plugs on each PC board ONE AT A TIME and apply a small amount of Deoxit contact cleaner on the pins and reseat them. Often can cause a problem radio to come alive.

43751. Resistance Checks TS-830 Audio Board

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-31 15:35:36 UTC

Don:

While you have the Audio board folded over to replace Q34 suggest you check the DET signal return lead from Audio Board Conn 1 and IF Board Conn 11 as follows.

1. With both connectors plugged in measure from Conn 1 Pin 1 to Conn 11 Pin 2 = 0.20 ohms or less.

2. Locate TPG on Audio board diagonally from TP-1 and below Jumper J6. There is no ground post at this point just a hole and at bottom of hole is the silver/aluminum ground foil. This is the audio pre-amp ground plane.

3. Unplug Conn 1 and measure from Conn 1 Pin 1 (at the board mounted connector body and not at the pulled plug)to TPG = 0.10 ohms or less.

4. Measure from TPG to Chassis ground = 3k ohm or slightly less.

Re-land Conn 1.

Reminder the resistance at 12vdc regulated post to ground should be approx 40 ohms.

Terry K9TW

Don:

I forgot to mention with board folded over ideal time to check all the molex pin soldering especially Conn 1 where DET signal enters the board. I do this with Molex plugs plugged into board mounted connector body and use good lite and magnification and gently rock the plug side to side and observe for any pin movement in the solder cone.

Hi Matt,

Congratulations on your TS-820S acquisition and welcome to the forum. Of all the Yahoo forums on various radios, this one is by far the best in my opinion. If manuals did not come with your radio, be sure to get copies of both the operating and service manuals by downloading off of the net (or available on eBay), so you have a good understanding of your radio. On this forum we have Terry and Mike who are absolute masters of these hybrids, plus there are many other knowledgeable members. I own a TS-530S and a TS-830S, and my first "modern" radio in my early days of hamming was a TS-520. Lately after I retired the hybrid bug bit me again and here I am. My TS-830S, purchased on eBay, needed quite a bit of advice from Terry on this forum before I could get it working and now it runs just fine.
Again welcome to hybrids and to the forum!
Scott, N6CIC

Hi Terry

Sure will give that a go and report it back.
I have a old parts power supply that has two 2200uf caps in it and i
will take those out to see if they might be a good candidate for
replacements.
I had a hard time to remove those caps[C83&C84] until i realized they
had another post on them i guess four stability.
C83 on the parts manual is marked wrong.
I have the $17 ESR meter i got on Ebay,and here is the readings i
got,The readings do very a bit when retested.
C83---2081 .13 ohms
C84 --1843 .36
C81 -- 765 .15
C82---3277 3.7

Don:

I would not install old 2200uf, pulls but up to you. Low voltage supplies are the heart of the rig and when have opportunity to upgrade I would do it.

I assume your first readings are UF followed by ESR.

As I previously noted determining what is good vs bad ESR takes a lot of experience and developing some rules of thumb. Especially helpful if have original data sheets that have the quality specs. Different quality levels means lower "normal" ESR.

Lower capacitance values typically means higher ESR value
Higher capacitance values typically means lower ESR value

1. ESR Less than 1 usually OK
2. ESR Greater than 10 usually BAD
3. What do you do about ESR values in between 1 and 10?

You essentially have to build a table from experience.

It appears C84 ESR is too high.

C82 capacitance should not be that high? Isnt it 3.3uf and not a 3300 uf? A 3.3uf then 3.7 esr could be good, but on edge of being too high. It is the noise decoupling cap for the zener and not typically that high a value of capacitance would be used. Wrong Xc?

As previously noted now that you have them out I would not put any of them back in. I dont like to repeat desolder/resolder on any of these boards and I avoid repeated exercising of the molex connectors. Try to do it once only for any rigs I work on for customers. To easy to induce obvious new failures or latent failures (cracked traces that manifest themselves later).

OK to study the capacitance and ESR values on pulls to see what you can learn from it, but silly at cost of new caps to re-install them. Also you can upgrade from the original 85 degree to modern 105 degree and low ESR filter caps for little money.

Anytime you see a bulged capacitor body or vent or white crystalline powder at the vent I like to ESR it. You can develop a table of capacitance vs ESR for all your removed caps and all the new ones you install to help you determine when ESR is too high.

In my opinion ESR testing is not the magic test set that some say it is. Maybe I just need more experience.

The whole idea of ESR testing in my mind was to be able to test in circuit with no need to lift capacitor lead. Kenwood Hybrid configuration does not facilitate that on very many capacitors mounted on PC boards. If I have to remove board and lift one lead to test suspect capacitor you can bet I am going to lift both leads and replace the 35 year old electrolytic while I am there.

I think I am correct on this but I would like confirmation before I try it. a transformer with input of 120 volts AC output of 220 AC connected backwards so that input on the 220 side would give me output of 120 on the other side. In other words using the primary as the secondary. oh yea, of course the 220 would have to be european type using two poles or wires instead of the three we use here in the U.S.
on the other hand if the transformer had a center tap on the 220 side could I use that with U.S. 220 ?

Terry
Yes you are right that ESR testing is not the magic test for sure,unless
you have the value from new stock[chart] and then i would not be too sure.
I did three repeat test's and they all varied,but close to same values
I am trying to find a supplier on Ebay that can supply them all of the caps.
I try to buy the 105 degree ones if i can get them.Mouser is carrying a
good selection now of higher temp ones.
The 2200uf's have a spacing of 7 mm.
By the way i did check the connector at Conn 1 and had a slight
movement,so i desoldered them all and resolded.

When in doubt pull them out

Yes that applying 220VAC on the secondary will produce 120VAC on the primary.

The same thing is done quite often with a filament transformer that has, for example, a 6.3VAC secondary filament winding that is connected to another transformer's 6.3VAC winding resulting in 120VAC on the primary of the transformer.

Make sure you do not exceed the current rating of the windings. Fuse the secondary winding that is now being used as the primary winding with the appropriate fuse. If you know the Volt amp rating (VA) you can calculate the approximate fuse using Amps = VA / Volts. For example, if the VA rating is 50 VA at 120VAC then the current will be 50 / 120 = .416 or 416 ma. a 3/4 amp fuse would work. If the reverse is done, 220VAC applied to the secondary resulting in 120VAC on the primary, AND the VA rating is still 50 VA, then the fuse rating would be 50 / 220 = .227amps or 227ma, a 1/2 amp fuse at 220VAC would work.

P.S. I am talking about 220volt and miliamps not megawatts. I am aware that the secondary winding could be and most probably is smaller gauge wire.

I think you mean TPG is 3.1k to chassis ground.

Measure 12vdc regulated post after you have remounted the new components and board folded back in place and heatsink resecured to chassis.

When you have board repaired and mounted and have good 12vdc let me know and we will go back to injecting audio at IF board DET output. No signal injecting on IF board path until we are 100% certain you have good audio.

43763. HO-13 L2 coil

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-07-31 20:53:22 UTC

I know this is not Kenwood but I thought I would try anyway.

I need the High Frequency L2 coil, part number 40-589, for my Heathkit HO-13 Ham Scan Panoramic Adaptor. I have the Low Frequency coil, 40-588, but that doesn't do me any good for a 3.395Mhz IF. I would rather align the scope with the proper oscillator coil rather than aligning it with the Low Frequency coil then do the alignment again if I can get the high frequency coil.

If you have one or know of a source, even a parts chassis of an HO-13 with the 40-589 L2 installed would be great, please let me know off the group, mycall at yahoo.com.

If you are trying to find the same radial lead spacing in a new cap I dont think that is going to be easy. Typically the new packages are smaller so the caps wont sit flush and look as nice on the board as the original. Maybe better to mount them with a little excess lead length that will allow getting on the leads in future if you need to.

Maybe Jim at HybridRestore sells exact package replacements?
